FortiOS™ Handbook

TABLE OF CONTENTS

Chapter 1 - What's New for FortiOS 5.2 ..... **44**

New features in FortiOS 5.2.12 44
New features in FortiOS 5.2.9 45
New features in FortiOS 5.2.8 45
New features in FortiOS 5.2.5 46
New features in FortiOS 5.2.4 48
New features in FortiOS 5.2.3 50
Interfaces on some FortiGate models are set in one-arm sniffer mode by default 50
Merge FGT-20C-ADSL and FWF-20C-ADSL 50
Log Viewer Improvements 51
Add AeroScout Inter-operabiliy testing 51
Add "Last connection time" Column in FortiView > VPN 51
FSSO agent support OU in group filters 52
Certificate GUI improvements 52
Improvement to WAN optimization feature 52
Add FortiAP LED dark support 52
Allow user to change VDOM operation mode more easily 53
Split 40G ports on some FortiGate models 53
Allow admin user to start/defer file system check if FGT was not shutdown properly 53
Cloud Sandboxing 53
Add a tooltip to remind users to activate FortiCloud to enable FortiSandbox cloud 53
Add warn about factory default certificate 53
Deep Flow 54
New features in FortiOS 5.2.2 54
Add allocator API and counters to scanunit 54
Add tooltips for application categories 56
Add broadcast/multicast suppression for local bridge mode ssid on the FAP side 56
Add hardware switch feature and SPAN functionality to 30D, 60, and 90D. Move POE ports out of Internal switch to independent interfaces 56
Disable performance statistics Logging 57
Improvements to firmware upload GUI dialog 57
Reimplementation of the session list as a part of FortiView to improve functionality and usability 58
Add GUI option to control the TLS versions for web administration 58

Cloud Wifi Support ... 58
Merge FWF/FGT-60D-3G4G and FGR-60D ... 58
Add FAP-224D/222C/25D/214B/21D/24D/112D/223C/321C support ... 59
Add support for more than 32k FortiClient configuration distribution through EC-NAC ... 60
Add a warning when using deep SSL inspection mode on security policy and SSL profile pages ... 60
Improve FSSO group GUI ... 60
Add Log Rate stats to System Resources widget ... 61
Add a command to export logs on local disk to external USB ... 61
Improve FortiView performance and add System Events, Admin Logins, and VPN ... 61
Integrate vmtools for FortiGate VMWare platforms ... 61
New features in FortiOS 5.2.1 ... 63
Include bandwidth and setup rate statistics in the event log ... 63
Allow export of collected emails ... 64
Ssl-ssh-profile is no longer mandatory when utm profiles are enabled ... 64
Disallow multiple destination interfaces on an IPsec firewall policy ... 64
Add a new diag test command for fnbamd ... 64
Add deregister all option in diagnose endpoint control registration ... 65
Redirect kernel messages to non-console terminals ... 65
Add FortiExtender supported 3G/4G modem list ... 65
Add a new option for STP forwarding ... 65
Suppress probe response based on threshold in wireless controller vap ... 66
Move global antivirus service settings into profile-protocol-options ... 66
Add Ekahau Blink Protocol support and reorganization for station-locate ... 66
Implement diagnose command to test flash SSD ... 67
Online help improvements ... 67
Add iprope check trace in flow trace ... 67
Log id-fields reference improvements ... 67
Add diagnose debug admin error-log command ... 68
Improve hasync debug ... 68
Improve interface list and switch mode ... 70
Wizard improvement ... 70
Allow VIP with port forwarding to permit ICMP ... 70
Support captive portal for block notification page ... 70
Add diagnose log clear-kernel-state command ... 71
Apply new LDAP Tree Browser design to the User Wizard and User Group page ... 71
New Join and try requests to FortiCloud for low-end models ... 71
Top Features ... 72
Unified Policy Management ... 72
FortiView Dashboards ... 72
SSL Inspection ... 73
Web Filtering ... 73

Application Control 73
IPsec VPN Creation Wizard 73
Captive Portal 73
FortiAP Management 74
Flow-based Antivirus 74
FortiExtender Support 74
Using a Virtual WAN Link for Redundant Internet Connections 74
Internet Key Exchange (IKE) 74
SSL VPN Creation 75
On-Net Status for FortiClient Devices 75
System Features 76
FortiExtender Support 76
Using a Virtual WAN Link for Redundant Internet Connections 78
FortiGuard Services 81
Netflow v9.0 82
DHCP Server Configuration 83
Improvements to Aggregate/Redundant Interfaces 84
Link Layer Discovery Protocol 86
CPU and Memory Usage per VDOM 86
Custom Languages for Guest Management and SSL VPN Portals 87
Packet Capture Options for Admin Profiles 88
FortiCloud Modem List 88
SPAN Support for Hard-Switch Interfaces 88
Setting the Service and AC-name in PPOE PADI/PADO Negotiations 89
Disabling FortiExplorer, the USB MGMT Port, and the Serial Console 89
Port Kernel Profiling 90
Using a Second Destination IP (VRDST) 90
Session Rate Stats per VDOM 90
Disable Honoring the Don't-Fragment Flag 90
Disable Login Time Recording 91
Per-IP-Bandwidth-Usage Feature Removed 91
Modem Support 91
Usability Enhancements 92
FortiView Dashboards 92
FortiExplorer Setup Wizard Improvements 97
Interfaces List Improvements 98
Dragging Objects Between Policies in the Policy List 99
Cloning Table Objects 99
DHCP-related Improvements in the Web-based Manager 99
System Resources Widget 99
License Information Widget 100
USB Modem Widget 100

New Feature Settings Preset 101
Improved Banned User List Page 101
Replacement Message Improvements 101
Sorting and Filtering Support for the Virtual IP list 101
Web-based Manager Options for the FortiGate-30D 101
Firewall 102
Menu Simplification 102
Unified Policy Management 103
Importing LDAP Users for a Security Policy 104
Dynamic VIP According to DNS Translation 105
GTP Rate Limiting 105
Object UUID Support 106
Configuring the Class of Service Bit 106
Hairpinning for NAT64 and NAT46 107
Maximum Number of Available Virtual IPs Increased 107
Security Profiles 108
Menu and Options Simplification 108
SSL Inspection 114
Web Filtering 116
Application Control 119
Flow-based Antivirus 121
Intrusion Protection System (IPS) 122
Vulnerability Scanning Visibility 123
Removed IM Proxy Options from the CLI 123
Client Reputation 123
IPsec VPN 124
VPN Creation Wizard 124
Internet Key Exchange (IKE) 126
Dynamic IPsec Route Control 128
Default Lifetimes and Proposal Values 129
Prioritizing DH Group Configuration 129
IPv6 Support for IPsec Phase 2 130
IPsec VPN Support with the FortiController-5103B 131
SSL VPN 132
SSL VPN Configuration 132
ECDSA Local Certificates 132
Host Security Check Error Replacement Message 133
Authentication 134
Captive Portal 134
User Authentication via a POP3 Server 135
Limiting Guest User Accounts 135
Nested Group Search in LDAP Authentication 136

Password Length for User Authentication 136
Certificates for Policy Authentication 136
Authentication Blackouts 136
Single Sign-On for Guest Accounts 137
Managing Devices 138
On-Net Status for FortiClient Devices 138
Endpoint Licenses 138
URL Filter Lists in Endpoint Control 139
FortiGuard Categories Consistency with FortiClient 139
Default Device Groups 139
Device Detection for Traffic Not Flowing Through the FortiGate 139
Wireless Networking 140
FortiAP Management 140
Captive Portal for WiFi 142
New Wireless Health Charts 142
RADIUS Accounting 143
802.11ac and DARRP Support 143
Date Channel DTLS in Kernel 143
IPv6 144
IPv6 Address Ranges 144
TCP MSS Values 144
RSSO Support 144
FortiManager Connections 145
Geographical Database 145
High Availability 146
DHCP and PPPOE Support for Active-Passive Mode 146
VRRP Support 146
Trigger Failover 147
Synchronizing a GTP Tunnel over Physical Ports 147
IPv6 Management Interface Gateway 147
WAN Optimization, Web Cache, and Explicit Proxy 148
Explicit Proxy Policy Table - for explicit web proxy, explicit FTP proxy and WAN optimization policies 148
Distributing Explicit Web Proxy Traffic to Multiple CPU Cores 148
Proxy Header Control 149
Explicit Web Proxy SOCKS services support for TCP and UDP traffic 150
Preventing the explicit web proxy from changing source addresses 150
Explicit web proxy firewall address URL patterns 150
Advanced Routing 152
BGP Neighbor Groups 152
OSPF Fast Hello 152
BGP Conditional Advertising 153

Source and Destination IP-based Mode for ECMP 153
Policy Routes 153
Logging and Reporting 154
Traffic and UTM Logging Improvements 154
FortiGate Daily Security Report 154
GTP Logging Improvements 155
Flash-based Logging Disabled on Some Models 156
Accessing Policy-specific Logs from the Policy List 156
IPS Event Context Data in Log Messages 156
Sniffer Traffic Log 156
Selecting Sources for Reports 156
Threat Weight 157
Disk Usage Information in System Event Logs 157
Event Log Generated When a Crash Occurs 157
Displaying FortiFlow Names 157
Other New Features 158
SIP Traffic is Handled by the SIP ALG by Default 158
Changing the Header Name of Load Balanced HTTP/HTTPS Traffic 158
TOS and DSCP Support for Traffic Mapping 159
RFC List 160
Chapter 2 - Getting Started 161
Differences between Models 162
Features 162
Names 162
Menus 162
Installation 163
NAT/Route Mode vs Transparent Mode 163
Installing a FortiGate in NAT/Route Mode 163
Installing a FortiGate in Transparent Mode 168
Troubleshooting your FortiGate Installation 170
Using Port Pairing to Simplify Transparent Mode 172
Using the Web-Based Manager 174
Connecting to the web-based manager 174
Menus 177
Dashboards 178
Feature settings 193
Information tables 194
Text strings 195
Basic Administration 197
Registration 197
System Settings 197
Firmware 202

FortiGuard 210
FortiCloud 220
Administrators 222
Passwords 232
Configuration Backups 233
Next Steps 240
Best Practices 240
The FortiGate Cookbook 240
The Fortinet Video Library 240
The FortiOS Handbook 240
Chapter 3 - Advanced Routing 241
Advanced Static Routing 242
Routing concepts 242
Static routing tips 257
Policy routing 258
Transparent mode static routing 262
Static routing example 263
Advanced static routing example: ECMP failover and load balancing 271
Dynamic Routing Overview 279
What is dynamic routing? 279
Comparison of dynamic routing protocols 282
Choosing a routing protocol 287
Dynamic routing terminology 288
IPv6 in dynamic routing 293
Routing Information Protocol (RIP) 295
RIP background and concepts 295
Troubleshooting RIP 307
Simple RIP example 311
RIPng — RIP and IPv6 326
Border Gateway Protocol (BGP) 332
BGP background and concepts 332
Troubleshooting BGP 345
Dual-homed BGP example 350
Redistributing and blocking routes in BGP 363
Open Shortest Path First (OSPF) 371
OSPF Background and concepts 371
Troubleshooting OSPF 383
Basic OSPF example 385
Advanced inter-area OSPF example 397
Controlling redundant links by cost 408
Intermediate System to Intermediate System Protocol(IS-IS) 412
IS-IS background and concepts 412

How IS-IS works 413
Troubleshooting IS-IS 418
Simple IS-IS example 421
Network layout and assumptions 422
Expectations 423
CLI configuration 423
Verification 425
Troubleshooting 428
Chapter 4 - Authentication 429
Change log 429
Introduction to authentication 431
What is authentication? 431
Methods of authentication 431
Types of authentication 433
Single Sign-On authentication for users 436
User's view of authentication 437
FortiGate administrator's view of authentication 437
General authentication settings 438
Authentication servers 440
FortiAuthenticator servers 440
RADIUS servers 440
LDAP servers 445
TACACS+ servers 455
POP3 servers 456
SSO servers 456
RSA ACE (SecurID) servers 458
Users and user groups 463
Users 463
User groups 477
Managing Guest Access 483
Configuring guest user access 483
Guest access in a retail environment 485
Configuring authenticated access 489
Authentication timeout 489
Password policy 490
Authentication protocols 492
Authentication in Captive Portals 492
Authentication in security policies 492
Authentication replacement messages 493
VPN authentication 501
Captive portals 506
Introduction to Captive Portals 506

Configuring a captive portal 506
Customizing captive portal pages 508
Certificate-based authentication 514
What is a security certificate? 514
Certificates overview 515
Managing X.509 certificates 518
Configuring certificate-based authentication 526
Example — Generate a CSR on the FortiGate unit 528
Example — Generate and Import CA certificate with private key pair on OpenSSL 529
Example — Generate an SSL certificate in OpenSSL 530
Single Sign-On using a FortiAuthenticator unit 533
User's view of FortiAuthenticator SSO authentication 533
Administrator's view of FortiAuthenticator SSO authentication 533
Configuring the FortiAuthenticator unit 534
Configuring the FortiGate unit 534
Configuring the FortiClient SSO Mobility Agent 535
Viewing SSO authentication events on the FortiGate unit 536
Single Sign-On to Windows AD 537
Introduction to Single Sign-On with Windows AD 537
Configuring Single Sign On to Windows AD 537
FortiOS FSSO log messages 542
Testing FSSO 543
Troubleshooting FSSO 543
Agent-based FSSO 545
Introduction to agent-based FSSO 545
FSSO NTLM authentication support 551
Agent installation 554
Configuring the FSSO Collector agent for Windows AD 560
Configuring the FSSO TS agent for Citrix 571
Configuring FSSO with Novell networks 572
Configuring FSSO Advanced Settings 574
Configuring FSSO on FortiGate units 579
FortiOS FSSO log messages 585
Testing FSSO 586
Troubleshooting FSSO 587
SSO using RADIUS accounting records 589
User's view of RADIUS SSO authentication 589
Configuration Overview 589
Configuring the RADIUS server 589
Creating the FortiGate RADIUS SSO agent 590
Defining local user groups for RADIUS SSO 591
Creating security policies 592

Example: webfiltering for student and teacher accounts 593
Monitoring authenticated users 596
Monitoring firewall users 596
Monitoring SSL VPN users 596
Monitoring IPsec VPN users 597
Monitoring users Quarantine 597
Examples and Troubleshooting 599
Firewall authentication example 599
LDAP Dial-in using member-attribute example 605
RADIUS SSO example 607
Troubleshooting 614
Chapter 5 - Best Practices 616
Overview 616
General Considerations 616
Customer service and technical support 616
Fortinet Knowledge Base 616
System and performance 618
Performance 618
Shutting down 618
Migration 619
Information gathering 619
Object and policy migration 619
Testing and validation 619
Going live and obtaining feedback 620
Adding new services 620
Environmental specifications 621
Grounding 621
Rack mounting 621
Firmware 623
Firmware change management 623
Performing a firmware upgrade 626
Performing a firmware downgrade 627
Performing a configuration backup 627
Security Profiles (AV, Web Filtering etc.) 630
Firewall 630
Security 630
Authentication 631
Antivirus 631
Antispam 631
Intrusion Prevention System (IPS) 631
Email filter 632
URL filtering 632

Web filtering 633
Patch management 633
Policy configuration 633
Networking 635
Routing configuration 635
Advanced routing 635
Network Address Translation (NAT) 636
Transparent Mode 636
Using Virtual IPs (VIPs) 636
FGCP High Availability 637
Heartbeat interfaces 637
Interface monitoring (port monitoring) 638
WAN Optimization 639
Virtual Domains (VDOMs) 641
Per-VDOM resource settings 641
Virtual domains in NAT/Route mode 641
Virtual clustering 641
Explicit proxy 642
Wireless 643
Encryption and authentication 643
Geographic location 643
Network planning 643
Lowering the power level to reduce RF interference 644
Wireless client load balancing 644
Local bridging 644
Advertising SSIDs 645
Using static IPs in a CAPWAP configuration 645
Logging and reporting 646
Log management 646
System memory and hard disks 647
Chapter 6 - FortiOS Carrier 648
Overview of FortiOS Carrier features 649
Overview 649
Registering FortiOS Carrier 650
MMS background 650
How FortiOS Carrier processes MMS messages 654
MMS protection profiles 663
Bypassing MMS protection profile filtering based on carrier endpoints 664
Applying MMS protection profiles to MMS traffic 664
GTP basic concepts 664
GPRS network common interfaces 672
Packet flow through the GPRS network 673

SCTP 675
Carrier web-based manager settings 680
MMS Security features 727
Why scan MMS messages for viruses and malware? 727
MMS virus scanning 728
Sender notifications and logging 735
MMS content-based Antispam protection 738
MMS DLP archiving 740
Message flood protection 742
Overview 742
Setting message flood thresholds 743
Notifying administrators of floods 745
Example — three flood threshold levels with different actions for each threshold 745
Notifying message flood senders and receivers 748
Viewing DLP archived messages 749
Order of operations: flood checking before duplicate checking 749
Bypassing message flood protection based on user's carrier endpoints 750
Configuring message flood detection 750
Sending administrator alert notifications 751
Duplicate message protection 754
Overview 754
Using message fingerprints to identify duplicate messages 755
Messages from any sender to any recipient 756
Setting duplicate message thresholds 756
Duplicate message actions 756
Notifying duplicate message senders and receivers 757
Viewing DLP archived messages 759
Order of operations: flood checking before duplicate checking 759
Bypassing duplicate message detection based on user's carrier endpoints 759
Configuring duplicate message detection 759
Sending administrator alert notifications 759
Configuring GTP on FortiOS Carrier 762
GTP support on the Carrier-enabled FortiGate unit 762
Configuring General Settings on the Carrier-enabled FortiGate unit 764
Configuring Encapsulated Filtering in FortiOS Carrier 764
Configuring the Protocol Anomaly feature in FortiOS Carrier 766
Configuring Anti-overbilling in FortiOS Carrier 766
Logging events on the Carrier-enabled FortiGate unit 767
GTP message type filtering 769
Common message types on carrier networks 769
Configuring message type filtering in FortiOS Carrier 771
GTP identity filtering 777

IMSI on carrier networks 777
Other identity and location based information elements 777
Configuring APN filtering in FortiOS Carrier 780
Configuring IMSI filtering in FortiOS Carrier 781
Configuring advanced filtering in FortiOS Carrier 782
Troubleshooting 785
FortiOS Carrier diagnose commands 785
Applying IPS signatures to IP packets within GTP-U tunnels 787
GTP packets are not moving along your network 787
Chapter 7 - Compliance 792
Compliance 792
Introduction 792
Configuring FortiGate units for PCI DSS compliance 793
Chapter 8 - Deploying Wireless Networks 809
Introduction to wireless networking 810
Wireless concepts 810
Security 811
Authentication 813
Wireless networking equipment 813
Automatic Radio Resource Provisioning 814
Configuring a WiFi LAN 815
Overview of WiFi controller configuration 815
Setting your geographic location 817
Creating a FortiAP Profile 817
Defining a wireless network interface (SSID) 819
Dynamic VLAN assignment 828
Configuring user authentication 830
Configuring firewall policies for the SSID 832
Configuring the built-in access point on a FortiWiFi unit 833
Access point deployment 834
Overview 834
Network topology for managed APs 834
Discovering and authorizing APs 836
Advanced WiFi controller discovery 841
Wireless client load balancing for high-density deployments 842
LAN port options 844
Preventing IP fragmentation of packets in CAPWAP tunnels 846
Wireless Mesh 847
Overview of Wireless Mesh 847
Configuring a meshed WiFi network 851
Configuring a point-to-point bridge 853
Combining WiFi and wired networks with a software switch 855

Combining WiFi and wired networks with a software switch 855
FortiAP local bridging (Private Cloud-Managed AP) 857
Using bridged FortiAPs to increase scalability 860
Using Remote WLAN FortiAPs 861
Configuring the FortiGate for remote FortiAPs 861
Configuring the FortiAP units 862
Preauthorizing FortiAP units 863
Features for high-density deployments 863
Broadcast packet suppression 863
Multicast to unicast conversion 863
Ignore weak or distant clients 864
Turn off 802.11b protocol 864
Limit power 864
Use frequency band load-balancing 865
AP load balancing 865
Application rate-limiting 866
Protecting the WiFi Network 867
Wireless IDS 867
WiFi data channel encryption 868
Wireless network monitoring 870
Monitoring wireless clients 870
Monitoring rogue APs 870
Suppressing rogue APs 876
Monitoring wireless network health 876
Configuring wireless network clients 877
Windows XP client 877
Windows 7 client 882
Mac OS client 886
Linux client 888
Troubleshooting 890
Wireless network examples 893
Basic wireless network 893
A more complex example 898
Using a FortiWiFi unit as a client 909
Use of client mode 909
Configuring client mode 910
Support for location-based services 911
Overview 911
Configuring location tracking 911
Viewing device location data on the FortiGate unit 911
Reference 913
FortiAP web-based manager 914

Wireless radio channels 916
FortiAP CLI 917
Chapter 9 - Firewall 924
FortiGate Firewall Components 924
How does a FortiGate protect your network? 925
Firewall concepts 927
What is a firewall? 927
IPv6 930
NAT 938
How packets are handled by FortiOS 946
FortiGate modes 948
Quality of Service 948
Interfaces and zones 949
Firewall objects 951
UUID support 951
Addresses 951
Address groups 960
Virtual IPs 961
Virtual IP groups 964
IP pools 965
Services and TCP ports 968
Firewall schedules 999
Schedule groups 1001
Security policies 1003
Firewall policies 1003
Security profiles 1010
SSL/SSH inspection 1015
Identity-based policies 1021
VPN policies 1023
Interface policies 1023
DoS protection 1024
Local-In policies 1029
Security policy 0 1030
Deny policies 1031
Accept policies 1031
Fixed port 1031
Endpoint security 1031
Traffic logging 1032
Quality of service 1033
Policy Monitor 1034
Network defense 1036
Monitoring 1036

Blocking external probes 1036
Defending against DoS attacks 1041
GUI and CLI - what you may not know 1045
Mouse tricks 1046
Changing the default column setting on the policy page 1047
Naming rules and restrictions 1049
Character restrictions 1050
Numeric values 1051
Numeric values 1052
Selecting options from a list 1053
Enabling or disabling options 1054
To enable or disable optionally displayed features 1056
Building firewall objects and policies 1056
Building firewall objects and policies 1057
Example: IPv4 firewall addresses 1058
Example: IPv6 firewall addresses 1060
Example: FQDN address 1062
Changing the TTL of a FQDN address 1062
Example: Geography-based address 1063
Example: IPv4 address group 1063
Example: IPv6 address group 1064
Example: Multicast address 1065
Example: Service category 1066
Example: TCP/UDP/SCTP service 1067
Example: ICMP service 1069
Example: ICMPv6 service 1070
Example: Service group 1071
Example: Virtual IP address 1072
Example: IP pool 1074
Example: Central NAT table 1075
Example: Firewall schedule - recurring 1076
Example: Firewall schedule - one-time 1077
Example: Schedule group 1078
Example: Proxy option 1079
Example: DoS policy 1082
Multicast forwarding 1086
Sparse mode 1086
Dense mode 1087
Multicast IP addresses 1088
PIM Support 1088
Multicast forwarding and FortiGate units 1089
Configuring FortiGate multicast forwarding 1090

Multicast routing examples 1094
Chapter 10 - FortiView 1120
FortiView 1120
Overview 1121
FortiView consoles 1129
Reference 1136
Troubleshooting FortiView 1147
Chapter 11 - Hardening 1148
Hardening your FortiGate 1148
Install the FortiGate unit in a physically secure location 1148
Maintain the firmware 1148
Add new administrator accounts 1149
Change the admin account name and limit access to this account 1149
Only allow administrative access to the external interface when needed 1150
When enabling remote access, configure Trusted Hosts and Two-factor Authentication 1150
Change the default administrative port to a non-standard port 1151
Modify the device name 1151
Register with support services 1151
Maintain short login timeouts 1151
Enable automatic clock synchronization 1152
Enable Password Policy 1152
Modify administrator account Lockout Duration and Threshold values 1152
Disable auto installation via USB 1153
Configure auditing and logging 1153
Chapter 12 - Hardware Acceleration 1154
Hardware acceleration overview 1155
Content processors (CP4, CP5, CP6 and CP8) 1155
Security processors (SPs) 1157
Network processors (NP1, NP2, NP3, NP4 and NP6) 1160
Enabling strict protocol header checking disables all hardware acceleration 1165
sFlow and NetFlow and hardware acceleration 1165
Checking that traffic is offloaded by NP processors 1165
Controlling IPS NPx and CPx acceleration 1167
Dedicated Management CPU 1168
Offloading flow-based content inspection with NTurbo and IPSA 1168
NP6 Acceleration 1170
NP6 session fast path requirements 1170
NP6 processors and traffic shaping 1172
Viewing your FortiGate NP6 processor configuration 1172
Optimizing NP6 performance by distributing traffic to XAUI links 1173
Increasing NP6 offloading capacity using link aggregation groups (LAGs) 1175

Configuring Inter-VDOM link acceleration with NP6 processors 1175
Configuring individual NP6 processors 1178
Enabling per-session accounting for offloaded NP6 sessions 1184
FortiGate NP6 architectures 1185
FortiGate-300D fast path architecture 1185
FortiGate-400D fast path architecture 1185
FortiGate-500D fast path architecture 1186
FortiGate-600D fast path architecture 1187
FortiGate-800D fast path architecture 1188
FortiGate-900D fast path architecture 1190
FortiGate-1000D fast path architecture 1192
FortiGate-1200D fast path architecture 1194
FortiGate-1500D fast path architecture 1197
FortiGate-1500DT fast path architecture 1198
FortiGate-3000D fast path architecture 1200
FortiGate-3100D fast path architecture 1202
FortiGate-3200D fast path architecture 1203
FortiGate-3700D fast path architecture 1206
FortiGate-3700DX fast path architecture 1210
FortiGate-3810D fast path architecture 1214
FortiGate-3815D fast path architecture 1216
FortiGate-5001D fast path architecture 1217
FortiController-5902D fast path architecture 1219
NP4 Acceleration 1222
Viewing your FortiGate's NP4 configuration 1222
Configuring NP4 traffic offloading 1223
Increasing NP4 offloading capacity using link aggregation groups (LAGs) 1224
NP4 traffic shaping offloading 1225
NP4 IPsec VPN offloading 1225
NP4 IPsec VPN offloading configuration example 1226
Configuring Inter-VDOM link acceleration with NP4 processors 1230
Offloading NP4 anomaly detection 1234
FortiGate NP4 architectures 1237
FortiGate-600C 1237
FortiGate-800C 1238
FortiGate-1000C 1239
FortiGate-1240B 1240
FortiGate-3040B 1241
FortiGate-3140B 1242
FortiGate-3140B — load balance mode 1243
FortiGate-3240C 1243
FortiGate-3600C 1245

FortiGate-3950B and FortiGate-3951B 1246
FortiGate-3950B and FortiGate-3951B — load balance mode 1248
FortiGate-5001C 1249
FortiGate-5001B 1250
Setting switch-mode mapping on the ADM-XD4 1251
Hardware acceleration diagnose commands 1251
diagnose sys session/session6 list (IPv4, IP6, NAT46, NAT64, and IPsec session information) 1251
diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions) 1255
diagnose npu np6 ipsec-stats (NP6 IPsec statistics) 1256
diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions) 1257
diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions) 1258
diagnose npu np6 dce <np6-id> (number of dropped NP6 packets) 1258
diagnose hardware deviceinfo nic <interfac-name> (number of packets dropped by an interface) 1259
dianose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs) 1260
Chapter 13 - High Availability 1261
FortiOS 5.2 HA new features 1262
Solving the High Availability problem 1263
FortiGate Cluster Protocol (FGCP) 1263
FortiGate Session Life Support Protocol (FGSP) 1265
VRRP 1266
Fortinet redundant UTM protocol (FRUP) 1266
Session-Aware Load Balancing Clustering (SLBC) 1267
Enhanced Load Balancing Clustering (ELBC) 1268
Content clustering 1268
An introduction to the FGCP 1270
About the FGCP 1270
Synchronizing the configuration (and settings that are not synchronized) 1273
Preparing the FortiGates before setting up a FGCP cluster 1274
Configuring FortiGate units for FGCP HA operation 1275
Active-passive and active-active HA 1278
Identifying the cluster and cluster units 1279
Device failover, link failover, and session failover 1280
Primary unit selection 1280
HA override 1288
FortiGate HA compatibility with DHCP and PPPoE 1292
HA and distributed clustering 1293
Clusters of three or four FortiGate units 1293
Disk storage configuration and HA 1296
FGCP HA terminology 1298

HA web-based manager options 1302
FGCP high availability best practices 1304
FGCP HA terminology 1306
HA GUI options 1309
FGCP configuration examples and troubleshooting 1313
About the examples in this chapter 1313
How to set up FGCP clustering (recommended steps) 1313
Setting up two new FortiGates as an FGCP cluster 1319
Adding a new FortiGate to an operating cluster 1331
Active-active HA cluster in Transparent mode 1331
FortiGate-5000 active-active HA cluster with FortiClient licenses 1343
Converting a standalone FortiGate unit to a cluster 1353
Replacing a failed cluster unit 1358
FGCP HA with 802.3ad aggregated interfaces 1359
Example HA and redundant interfaces 1371
Troubleshooting HA clusters 1381
Virtual clusters 1387
Virtual clustering overview 1387
Configuring HA for virtual clustering 1389
Example virtual clustering with two VDOMs and VDOM partitioning 1391
Example inter-VDOM links in a virtual clustering configuration 1404
Troubleshooting virtual clustering 1406
Full mesh HA 1407
Full mesh HA overview 1407
Example full mesh HA configuration 1409
Troubleshooting full mesh HA 1419
Operating a cluster 1421
Operating a cluster 1421
Operating a virtual cluster 1421
Managing individual cluster units using a reserved management interface 1422
Managing individual cluster units in a virtual cluster 1426
The primary unit acts as a router for subordinate unit management traffic 1426
Clusters and FortiGuard services 1427
Clusters and logging 1428
Clusters and SNMP 1431
Adding FortiClient licenses to a cluster 1435
Cluster members list 1437
Virtual cluster members list 1438
Viewing HA statistics 1438
Changing the HA configuration of an operating cluster 1438
Changing the HA configuration of an operating virtual cluster 1439
Changing the subordinate unit host name and device priority 1439

Upgrading cluster firmware 1439
Downgrading cluster firmware 1441
Backing up and restoring the cluster configuration 1442
Monitoring cluster units for failover 1442
Viewing cluster status from the CLI 1443
Disconnecting a cluster unit from a cluster 1451
Adding a disconnected FortiGate unit back to its cluster 1452
HA diagnose commands 1453
HA and failover protection 1455
About active-passive failover 1455
About active-active failover 1456
Device failover 1456
HA heartbeat and communication between cluster units 1457
Cluster virtual MAC addresses 1464
Synchronizing the configuration 1471
Synchronizing kernel routing tables 1480
Configuring graceful restart for dynamic routing failover 1482
Synchronizing IPsec VPN SAs 1484
Link failover (port monitoring or interface monitoring) 1485
Subsecond failover 1491
Remote link failover 1491
Session failover (session pick-up) 1496
WAN optimization and HA 1501
Failover and attached network equipment 1501
Monitoring cluster units for failover 1502
NAT/Route mode active-passive cluster packet flow 1502
Transparent mode active-passive cluster packet flow 1504
Failover performance 1506
HA and load balancing 1509
Load balancing overview 1509
Selecting a load balancing schedule 1511
Load balancing TCP and UDP sessions 1512
Using NP4 or NP6 processors to offload load balancing 1512
Configuring weighted-round-robin weights 1512
Dynamically optimizing weighted load balancing according to how busy cluster units are 1514
NAT/Route mode active-active cluster packet flow 1517
Transparent mode active-active cluster packet flow 1520
HA with FortiGate-VM and third-party products 1524
FortiGate-VM for VMware HA configuration 1524
FortiGate VM for Hyper-V HA configuration 1524
Troubleshooting layer-2 switches 1525

Failover issues with layer-3 switches 1525
Changing spanning tree protocol settings for some switches 1525
Failover and attached network equipment 1526
Ethertype conflicts with third-party switches 1526
LACP, 802.3ad aggregation and third-party switches 1527
VRRP 1528
Configuring VRRP 1531
FortiGate Session Life Support Protocol (FGSP) 1535
Synchronizing the configuration 1537
Synchronizing UDP and ICMP (connectionless) sessions 1538
Synchronizing NAT sessions 1538
Synchronizing asymmetric sessions 1538
Synchronizing expectation sessions 1539
Security profile flow-based inspection and asymmetric traffic 1539
Notes and limitations 1540
Configuring FGSP HA 1540
Configuring the session synchronization link 1541
Basic example configuration 1541
Verifying FGSP configuration and synchronization 1544
Configuring FRUP 1546
FRUP and the mode of the FortiGate hardware switch 1546
FRUP configuration example 1547
Chapter 14 - IPsec VPN 1552
IPsec VPN concepts 1554
VPN tunnels 1554
VPN gateways 1555
Clients, servers, and peers 1557
Encryption 1557
Authentication 1558
Phase 1 and Phase 2 settings 1559
Security Association 1560
IKE and IPsec packet processing 1560
IPsec VPN overview 1563
Types of VPNs 1563
Planning your VPN 1565
General preparation steps 1566
How to use this guide to configure an IPsec VPN 1567
IPsec VPN in the web-based manager 1568
Phase 1 configuration 1568
Phase 2 configuration 1574
Concentrator 1580
IPsec Monitor 1580

Phase 1 parameters 1581
Overview 1581
Defining the tunnel ends 1582
Choosing Main mode or Aggressive mode 1582
Choosing the IKE version 1583
Authenticating the FortiGate unit 1583
Authenticating remote peers and clients 1586
Defining IKE negotiation parameters 1591
Using XAuth authentication 1595
Dynamic IPsec route control 1596
Phase 2 parameters 1598
Phase 2 settings 1598
Configuring the Phase 2 parameters 1600
Defining VPN security policies 1603
Defining policy addresses 1603
Defining VPN security policies 1604
Gateway-to-gateway configurations 1609
Configuration overview 1609
General configuration steps 1611
Configuring the two VPN peers 1611
How to work with overlapping subnets 1616
Testing 1620
Hub-and-spoke configurations 1623
Configuration overview 1623
Configure the hub 1625
Configure the spokes 1629
Dynamic spokes configuration example 1633
Dynamic DNS configuration 1639
Dynamic DNS over VPN concepts 1639
Dynamic DNS topology 1641
General configuration steps 1643
Configure the dynamically-addressed VPN peer 1643
Configure the fixed-address VPN peer 1648
Testing 1652
FortiClient dialup-client configurations 1654
Configuration overview 1654
FortiClient-to-FortiGate VPN configuration steps 1659
Configure the FortiGate unit 1659
Configure the FortiClient Endpoint Security application 1663
Adding XAuth authentication 1663
FortiClient dialup-client configuration example 1663
FortiGate dialup-client configurations 1669

Configuration overview 1669
FortiGate dialup-client configuration steps 1671
Configure the server to accept FortiGate dialup-client connections 1672
Configure the FortiGate dialup client 1674
Supporting IKE Mode config clients 1676
Automatic configuration overview 1676
IKE Mode Config overview 1676
Configuring IKE Mode Config 1676
Example FortiGate unit as IKE Mode Config server 1680
Example FortiGate unit as IKE Mode Config client 1680
Internet-browsing configuration 1682
Configuration overview 1682
Creating an Internet browsing security policy 1683
Routing all remote traffic through the VPN tunnel 1684
Redundant VPN configurations 1686
Configuration overview 1686
General configuration steps 1687
Configure the VPN peers - route-based VPN 1688
Redundant route-based VPN configuration example 1690
Partially-redundant route-based VPN example 1703
Creating a backup IPsec interface 1710
Transparent mode VPNs 1711
Configuration overview 1711
Configure the VPN peers 1715
IPv6 IPsec VPNs 1717
Overview of IPv6 IPsec support 1717
Configuring IPv6 IPsec VPNs 1718
Site-to-site IPv6 over IPv6 VPN example 1719
Site-to-site IPv4 over IPv6 VPN example 1723
Site-to-site IPv6 over IPv4 VPN example 1726
L2TP and IPsec (Microsoft VPN) 1730
Overview 1730
Assumptions 1731
Configuring the FortiGate unit 1731
Configuring the Windows PC 1736
Troubleshooting 1737
GRE over IPsec (Cisco VPN) 1741
Overview 1741
Configuring the FortiGate unit 1741
Configuring the Cisco router 1747
Troubleshooting 1747
Protecting OSPF with IPsec 1750

Overview 1750
OSPF over IPsec configuration 1750
Creating a redundant configuration 1756
Redundant OSPF routing over IPsec 1758
Creating redundant IPsec tunnels on FortiGate 1 1758
Configuring IP addresses and OSPF on FortiGate 1 1758
Configuring firewall addresses on FortiGate 1 1759
Configuring security policies on FortiGate 1 1759
Creating redundant IPsec tunnels on FortiGate 2 1759
Configuring IP addresses and OSPF on FortiGate 2 1760
Configuring firewall addresses on FortiGate 2 1760
Configuring security policies on FortiGate 2 1761
Results 1761
OSPF over dynamic IPsec 1762
Configuring IPsec on FortiGate 1 1762
Configuring OSPF on FortiGate 1 1762
Adding policies on FortiGate 1 1763
Configuring IPsec on FortiGate 2 1763
Configuring OSPF on FortiGate 2 1763
Adding policies on FortiGate 2 1764
Verifying the tunnel is up 1764
Results 1764
BGP over dynamic IPsec 1765
Configuring IPsec on FortiGate 1 1765
Configuring BGP on FortiGate 1 1766
Adding policies on FortiGate 1 1766
Configuring IPsec on FortiGate 2 1766
Configuring BGP on FortiGate 2 1767
Adding policies on FortiGate 2 1767
Adding a static route on FortiGate 2 1767
Verifying the tunnel is up 1767
Results 1767
Logging and monitoring 1769
Monitoring VPN connections 1769
Logging VPN events 1770
Troubleshooting 1771
VPN troubleshooting tips 1775
General troubleshooting tips 1776
Chapter 15 - IPv6 1778
Possible addresses: 1778
IPv6 packet structure 1779
Benefits of IPv6 1779

IPv6 Features ... 1780
IPv6 policies ... 1780
IPv6 Network Address Translation ... 1792
ICMPv6 ... 1798
IPv6 in dynamic routing ... 1803
Dual stack routing ... 1804
IPv6 tunnelling ... 1804
SIP over IPv6 ... 1805
New Fortinet FortiGate IPv6 MIB fields ... 1806
IPv6 Per-IP traffic shaper ... 1807
DHCPv6 ... 1808
IPv6 forwarding ... 1808
Obtaining IPv6 addresses from an IPv6 DHCP server ... 1808
IPv6 Configuration ... 1809
IPv6 address groups ... 1809
IPv6 address ranges ... 1810
IPv6 firewall addresses ... 1811
ICMPv6 ... 1813
IPv6 IPsec VPN ... 1813
TCP MSS values ... 1826
BGP and IPv6 ... 1826
RIPng — RIP and IPv6 ... 1827
IPv6 RSSO support ... 1833
IPv6 IPS ... 1833
Blocking IPv6 packets by extension headers ... 1833
IPv6 Denial of Service policies ... 1834
Configure hosts in an SNMP v1/2c community to send queries or receive traps ... 1834
IPv6 PIM sparse mode multicast routing ... 1834
Chapter 16 - Life of a Packet ... 1835
Life of a Packet ... 1835
Packet flow ... 1836
Comparison of inspection types ... 1843
Client/Server connection packet flow example ... 1845
Routing table update packet flow example ... 1847
Dialup IPsec VPN with Application control example ... 1848
Chapter 17 - Load Balancing ... 1850
Before you begin ... 1850
How this chapter is organized ... 1850
Configuring load balancing ... 1851
Load balancing and other FortiOS features ... 1852
Configuring load balancing from the web-based manager ... 1852
Configuring load balancing from the CLI ... 1854

Load balancing methods 1854
Session persistence 1856
Real servers 1856
Health check monitoring 1858
Load balancing limitations 1860
Monitoring load balancing 1860
Load balancing diagnose commands 1861
Basic load balancing configuration example 1863
HTTP and HTTPS load balancing, multiplexing, and persistence 1867
SSL/TLS load balancing 1871
IP, TCP, and UDP load balancing 1879
Load balancing configuration examples 1880
Example HTTP load balancing to three real web servers 1880
Example Basic IP load balancing configuration 1885
Example Adding a server load balance port forwarding virtual IP 1886
Example Weighted load balancing configuration 1888
Example HTTP and HTTPS persistence configuration 1891
Chapter 18 - Logging and Reporting 1896
Logging and reporting overview 1897
What is logging? 1897
FortiOS features available for logging 1898
Log messages 1903
Log files and types 1910
Log database and datasets 1911
Log devices 1913
Reports 1917
Best Practices: Log management 1919
Logging and reporting for small networks 1921
Modifying default log device settings 1921
Configuring the backup solution 1923
Modifying the default FortiOS report 1924
Logging and reporting for large networks 1925
Modifying default log device settings 1925
Configuring the backup solution 1927
Modifying the default FortiOS report 1929
Uploading the corporate images 1930
Advanced logging 1932
Configuring logging to multiple Syslog servers 1932
Using Automatic Discovery to connect to a FortiAnalyzer unit 1933
Activating a FortiCloud account for logging purposes 1933
Viewing log storage space 1934
Customizing and filtering log messages 1934

Viewing logs from the CLI 1935
Configuring NAC quarantine logging 1935
Logging local-in policies 1936
Tracking specific search phrases in reports 1939
Reverting modified report settings to default settings 1940
Troubleshooting and logging 1941
Using log messages to help in troubleshooting issues 1941
Connection issues between FortiGate unit and logging devices 1942
Log database issues 1942
Logging daemon (Miglogd) 1944
Chapter 19 - Managing Devices 1945
Managing “bring your own device” 1946
Device monitoring 1946
Device Groups 1947
Controlling access with a MAC Address Access Control List 1947
Security policies for devices 1948
Creating device policies 1949
Endpoint Protection 1951
Endpoint Protection overview 1951
Configuration overview 1953
Creating a FortiClient profile 1954
Creating the registration key 1956
Enabling Endpoint Protection in security policies 1956
Configuring endpoint registration over a VPN 1957
Monitoring endpoints 1958
Modifying the Endpoint Protection replacement messages 1958
Vulnerability Scan 1959
Configuring vulnerability scans 1959
Running a vulnerability scan and viewing scan results 1961
Requirements for authenticated scanning and ports scanned 1961
Microsoft Windows hosts - domain scanning 1961
Chapter 20 - Managing a FortiSwitch with a FortiGate 1968
Managing a FortiSwitch with a FortiGate 1968
Introduction 1968
Getting Started 1970
VLAN Configuration 1975
Port Configuration 1979
Scenarios 1980
Chapter 21 - Security Profiles 1999
Security Profiles overview 2000
Traffic inspection 2000
Content inspection and filtering 2001

Security Profiles components 2003
Security Profiles/lists/sensors 2004
AntiVirus 2006
Antivirus concepts 2006
Enabling AntiVirus scanning 2019
Testing your antivirus configuration 2021
Example Scenarios 2021
Web filter 2027
Web filter concepts 2027
Inspection Modes 2029
FortiGuard Web Filtering Service 2030
Overriding FortiGuard website categorization 2033
SafeSearch 2039
YouTube Education Filter 2040
Static URL Filter 2040
Web content filter 2045
Advanced web filter configurations 2048
Configuring Web Filter Profiles 2052
Web filtering example 2057
Application control 2061
Application control concepts 2061
Application Control Actions 2062
Application considerations 2063
Working with other FortiOS components 2064
Application traffic shaping 2064
Application control monitor 2065
Enable application control 2065
Application control examples 2068
Intrusion protection 2071
IPS concepts 2071
Enable IPS scanning 2073
IPS processing in an HA cluster 2078
Configure IPS options 2078
Enable IPS packet logging 2081
IPS examples 2082
Custom Application & IPS Signatures 2089
Custom signature syntax 2089
Custom signature keywords 2090
Creating a custom signature to block access to example.com 2101
Creating a custom signature to block the SMTP “vrfy” command 2103
Creating a custom signature to block files according to the file's hash value 2104
Email filter 2106

Email filter concepts 2106
Email filter techniques 2106
Order of spam filtering 2110
Spam actions 2111
Email traffic types to inspect 2111
Configuring an Email Filters 2111
Email filter examples 2113
Data leak prevention 2116
Data leak prevention concepts 2116
DLP archiving 2122
Enable data leak prevention 2123
Creating/editing a DLP sensor 2124
DLP examples 2126
ICAP 2132
The Protocol 2132
Offloading using ICAP 2133
Configuration Settings 2133
Example ICAP sequence 2134
Example Scenario 2134
Other Security Profiles considerations 2137
Security Profiles and Virtual domains (VDOMs) 2137
Conserve mode 2137
SSL content scanning and inspection 2140
Using wildcards and Perl regular expressions 2143
Chapter 22 - SSL VPN 2148
Introduction to SSL VPN 2149
SSL VPN modes of operation 2150
Port forwarding mode 2152
Traveling and security 2153
SSL VPN and IPv6 2154
Basic configuration 2155
User accounts and groups 2155
Configuring SSL VPN web portals 2160
Configuring security policies 2167
Configuring encryption key algorithms 2173
Additional configuration options 2173
The SSL VPN client 2182
FortiClient 2182
Tunnel mode client configuration 2182
The SSL VPN web portal 2184
Connecting to the FortiGate unit 2184
Web portal overview 2184

Portal configuration 2186
Using the My Bookmarks widget 2192
Using the Connection Tool 2194
Tunnel-mode features 2198
Using the SSL VPN virtual desktop 2198
Using FortiClient 2199
Setup examples 2200
Secure Internet browsing 2200
Split Tunnel 2203
Multiple user groups with different access permissions 2205
Troubleshooting 2211
Chapter 23 - System Administration 2214
Using the CLI 2215
Connecting to the CLI 2215
Command syntax 2220
Sub-commands 2225
Permissions 2231
Tips 2231
Firmware 2243
Backing up the current configuration 2243
Restoring a configuration file 2243
Downloading firmware 2244
Testing new firmware 2245
Upgrading the firmware - web-based manager 2246
Upgrading the firmware - CLI 2247
Installing firmware from a system reboot using the CLI 2248
Reverting to a previous firmware version - web-based manager 2249
Reverting to a previous firmware version - CLI 2250
Configuration revision 2251
Controlled upgrade 2251
Interfaces 2253
Physical 2253
Interface settings 2255
Software switch 2261
Virtual Switch 2263
Loopback interfaces 2264
Redundant interfaces 2264
One-armed sniffer 2265
Aggregate Interfaces 2265
DHCP addressing mode on an interface 2267
PPPoE addressing mode on an interface 2268
Administrative access 2271

Wireless 2272
Interface MTU packet size 2272
Secondary IP addresses to an interface 2273
Virtual domains 2273
Virtual LANs 2275
Zones 2276
Probing interfaces 2277
Central management 2278
Adding a FortiGate to FortiManager 2278
Configuration through FortiManager 2280
Firmware updates 2280
FortiGuard 2281
Backup and restore configurations 2281
Administrative domains 2281
Monitoring 2283
Dashboard 2283
sFlow 2284
Monitor menus 2285
Logging 2285
Packet Capture 2289

Chapter 1 - What's New for FortiOS 5.2

This FortiOS Handbook chapter contains the following sections:

- New features in FortiOS 5.2.12 provides a brief description of features that were added to FortiOS 5.2.12.
- New features in FortiOS 5.2.9 provides a brief description of features that were added to FortiOS 5.2.9.
- New features in FortiOS 5.2.8 provides a brief description of features that were added to FortiOS 5.2.8.
- New features in FortiOS 5.2.5 provides a brief description of features that were added to FortiOS 5.2.5.
- New features in FortiOS 5.2.4 provides a brief description of features that were added to FortiOS 5.2.4.
- New features in FortiOS 5.2.3 provides a brief description of features that were added to FortiOS 5.2.3.
- New features in FortiOS 5.2.2 provides a brief description of features that were added to FortiOS 5.2.2.
- New features in FortiOS 5.2.1 provides a brief description of features that were added to FortiOS 5.2.1.
- Top Features described some of the most important new features in FortiOS 5.2.
- System Features contains information on features connected to global settings.
- Usability Enhancements describes some enhancements that make the web-based manager easier to use and more effective.
- The next sections deal with new features for specific areas of network configuration:
  - Firewall
  - Security Profiles
  - IPsec VPN
  - SSL VPN
  - Authentication
  - Managing Devices
  - Wireless Networking
  - IPv6
  - High Availability
  - WAN Optimization, Web Cache, and Explicit Proxy
  - Advanced Routing
  - Logging and Reporting
- Other New Features contains information about other features that have been added in FortiOS 5.2.
- RFC List contains information about RFCs that are supported by the new features.

New features in FortiOS 5.2.12

Most development work in FortiOS 5.2.12 involved resolving issues. However, there were a few new features as well.

Stackable VDOM licenses (269153)

VDOM licenses are now stackable, allowing you to buy additional licenses and stack them on top existing licenses to increase the number of VDOMs you can have.

New features in FortiOS 5.2.9

Most development work in FortiOS 5.2.9 involved resolving issues. However, there were a few new features as well.

Last session information saved in a crash log when an IPS engine crash occurs (378252)

Changes to FortiOS IPS and to the IPS engine version 3.170 now cause FortiOS to save a crash log with the last session information when an IPS crash occurs. This information can be used by Fortinet support to diagnose the cause of the crash.

Dynamic Frequency Selection (DFS) support added to the FortiAP-321C (369052)

FortiOS 5.2.9 now supports DFS for the FortiAP-321C.

New features in FortiOS 5.2.8

TLS 1.2 support for SSL offloading (241817)

You can use the following command to configure SSL offloading to support TLS 1.2:

```
config firewall vip
   edit <name>
      set type server-load-balance
      set server-type https
      set ssl-min-version tls-1.2
      set ssl-max-version tls-1.2
      ...
```

The default `ssl-min-version` is still `ssl-3.0` and the default `ssl-max-version` is still `tls-1.0` so you have to specifically set at least `ssl-max-version` to `tls-1.2` to enable TLS 1.2 support.

The following AES-GCM TLS 1.2-only cipher suites have also been added. These cipher suites are not supported by the CPx or NPx processors so if you select one of these, all processing is done without hardware acceleration.

TLS 1.2 support does not require setting `ssl-algorithm` to `custom` and configuring a custom cipher suite.

```
TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
TLS-DHE-DSS-WITH-AES-128-GCM-SHA256
TLS-DHE-RSA-WITH-AES-256-GCM-SHA384
TLS-DHE-DSS-WITH-AES-256-GCM-SHA384
TLS-ECDHE-RSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-RSA-WITH-AES-256-GCM-SHA384
TLS-ECDHE-ECDSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-ECDSA-WITH-AES-256-GCM-SHA384
TLS-RSA-WITH-AES-128-GCM-SHA256
TLS-RSA-WITH-AES-256-GCM-SHA384
```

You can use the following command to select one of these cipher suites:

```
config firewall vip
   edit <name>
      set type server-load-balance
      set server-type https
      set ssl-max-version tls-1.2
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 100
               set cipher TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
               ...
```

New features in FortiOS 5.2.5

The default Diffie-Hellman setting is 2048 (286801)

This change improves the security of Diffie-Hellman key generation. The default was 1024.

Simple, Wildcard & Regex options now available for per-user BWL (270165)

The **Allow users to override blocked categories** web filter profile feature (available on some FortiGate models) now allows users to use simple, wildcard and regex expressions to identify the URLs that are blocked.

This feature is also called per-user BWL. To be able to configure this feature from the GUI enter the following command:

```
config system global
   set per-user-bwl enable
end
```

Then go to **Security Profiles > Web Filtering**, edit a web filtering profile and select **Allow users to override blocked categories**. You can select a web filter profile that users can switch to. If the URLs in the web filter profile contain wildcards or regex expressions they will now work when selected for user overrides.

Use the following command to configure this feature from the CLI:

```
config webfilter profile
   edit <profile-name>
      set options per-user-bwl
         config override
            set profile
            ...
         end
   end
```

New diagnose traffictest command (280801)

```
diagnose traffictest {show | run -h arg | server-intf | client-intf | port | proto}
```

Where -h arg can be

-f, --format [kmgKMG] format to report: Kbits, Mbits, KBytes, MBytes

-i, --interval # seconds between periodic bandwidth reports

-F, --file name xmit/recv the specified file

-A, --affinity n/n,m set CPU affinity

-V, --verbose more detailed output

-J, --json output in JSON format

-d, --debug emit debugging output

-v, --version show version information and quit

-h, --help show this message and quit

-b, --bandwidth #[KMG][/#] target bandwidth in bits/sec (0 for unlimited) (default %d Mbit/sec for UDP, unlimited for TCP) (optional slash and packet count for burst mode)

-t, --time # time in seconds to transmit for (default %d secs)

-n, --bytes #[KMG] number of bytes to transmit (instead of -t)

-k, --blockcount #[KMG] number of blocks (packets) to transmit (instead of -t or -n)

-l, --len #[KMG] length of buffer to read or write (default %d KB for TCP, %d KB for UDP)

-P, --parallel # number of parallel client streams to run

-R, --reverse run in reverse mode (server sends, client receives)

-w, --window #[KMG] TCP window size (socket buffer size)

-C, --linux-congestion <algo> set TCP congestion control algorithm (Linux only)

-M, --set-mss # set TCP maximum segment size (MTU - 40 bytes)

-N, --nodelay set TCP no delay, disabling Nagle's Algorithm

-4, --version4 only use IPv4

-6, --version6 only use IPv6

-S, --tos N set the IP 'type of service'

-L, --flowlabel N set the IPv6 flow label (only supported on Linux)

-Z, --zerocopy use a 'zero copy' method of sending data

-O, --omit N omit the first n seconds

-T, --title str prefix every output line with this string

--get-server-output get results from server

[KMG] indicates options that support a K/M/G suffix for kilo-, mega-, or giga-

Improve device identification (289921)

FortiFone devices are now identified by FortiOS as **Fortinet FON**. As Apple device detection have also been improved. FortiOS can now more reliably detect Mac OS, iPhone 6, Apple Watch, Microsoft tables and so on.

NP6 SynProxy Monitoring (218425)

New support for monitoring SynProxy and other DoS anomalies. The DoS policy list for both IPv4 and IPv6 displays active IPS meters, as shown by IP and by anomaly. With SynProxy activated, each destination IP will show results.

Maximum number of VLANs per interface increased for the FortiGate-30 Series (300032)

On the FortiGate-30 series products you can add up to 20 VLANs to a physical interface.

New features in FortiOS 5.2.4

This chapter lists new features added to FortiOS 5.2.4:

- The FortiGate-1000D now supports WAN Optimization. (275801)
- Split FortiGate-3810D 100G ports into ten 10G ports. For more information, see Split 40G ports on some FortiGate models on page 53(263829)

  Enter the following command to enable split ports for port1 and port2:

  ```
  config system global
     set split-port port23 port26
  end
  ```

  When you enter this command the FortiGate reboots and when it starts up the ports are split. The GUI and CLI would show these split ports as port1/1, port1/2, port1/3, ... port2/4.
- The `diagnose hardware device disk` command now includes the the `MAX SSD Disk` field, which shows the number of functioning SSD disks installed in the FortiGate. (271115)
- The correct checksum and file-size information, provided by the AV engine, is now added to anti-virus log messages. (261885)
- FGCP high availability supports BFD enabled BGP graceful restart after an HA failover. (255574)
- You can add a TFTP server address and a file name to a DHCP server configuration on one FortiGate to contain information that can be used by other FortiGates to download firmware updates from that TFTP server. This feature was added in a previous release but has been improved for FortiOS 5.2.4. (270160)

  Use the following command to add a TFTP server IP address of 10.10.10.5 and firmware image filename image.out to a FortiGate DHCP server:

  ```
  config system dhcp server
     edit 0
        ...
        set tftp-server 10.10.10.5
        set filename image.out
        ...
     end
  ```

  Then on a second FortiGate you can use the following command to cause the second FortiGate to retrieve the TFTP server IP address and firmware image filename and then download the firmware image and updgrade its firmware. In this example, the wan1 interface of the second FortiGate must be able to connect to the DHCP server of the original FortiGate.

  ```
  execute restore config dhcp wan1
  ```
- The default FortiGuard IPS and AV database update interval is now every 2 hours. Previously it was daily. (278772)

The new default configuration is:

```
config system autoupdate schedule
   set status enable
   set frequency every
   set time 2:60
end
```

where when `frequency` is set to `every` and `time` is `hh:mm`. If `mm` is 60 the update occurs at a random time within the final hour of the frequency. So a `time` of 2:60 means the update will occur some time in the second hour.

- WiFi logging improvements. (211695)

  Improved FortiWiFi local radio tx/rx statistics support.

  Band and channel_bonding fields added to oper-channel wireless event log.

  AP field is now accurately added to event log messages when radio settings are changed.

  Radio number(radioid) field added to wireless client activity event log.

- The extended IPS database is enabled by default for models with multiple CP8 content processors (300D/500D/1000D/1200D/1500D/3700D/3700DX/3810D/5001D). (238338)
- A new **block-security-risks** default webfilter profile has been added. In this profile FortiGuard Categories is selected,the Security Risk category is blocked, the Unrated catagory is set to warning and Rate URLs by Domain and IP Address is enabled. (278767)
- Changes to disk logging and WAN Optimization depending on the FortiGate hard disk configuration (adjustments/refinements to the changes made in 5.2.3). (266032)

  When you upgrade your FortiGate unit to FortiOS 5.2.4:

  - If your FortiGate unit has one hard disk, WAN Optimization settings will only be available from the CLI.
  - If your FortiGate unit has two hard disks, WAN Optimization settings will be available from the GUI and CLI.
  - WAN Optimization is not available if your FortiGate unit does not have a hard disk.

  The FortiOS 5.2.4 Feature/Platform Matrix shows WAN Optimization support by FortiGate model.

- For multi-hop EBGP peers, the nexthop is modified by the `route-map-out` setting. (183637)
- On FortiGate models that support it, the Fortinet_Factory certificate is now 2048 bits and uses SHA2. (284419)
- Explicit web proxy authentication performance improvements to prevent authenticated users from being blocked. (276065)
- Geography firewall addresses can now be added to explicit web proxy policies from the GUI and CLI. (281461)
- Add options for strict OCSP and strict CRL certificate checking (0258979)
  The new command options are:

  ```
  config vpn certificate setting
     set strict-crl-check {disable | enable}
     set strict-ocsp-check {disable | enable}
  end
  ```

  Enable `strict-crl-check` to enable strict mode CRL checking. If strict checking is not enabled and a certificate is found to be on a CRL list, the certificate can be used and a warning log message is written. If strict checking is enabled then all authentication actions that use this certificate fail in addition to the warning message being recorded.

  Enable `strict-ocsp-check` to enable strict mode OCSP checking. If strict checking is not enabled and an OCSP server responds with “cert status unknown” the certificate can be used and a

warning log message is written. If strict checking is enabled then all authentication actions that use this certificate fail in addition to the warning message being written.

New features in FortiOS 5.2.3

This chapter provides a brief introduction to the following features that were added to FortiOS 5.2.3. See the release notes for a complete list of new features/resolved issues in this release.

- Interfaces on some FortiGate models are set in one-arm sniffer mode by default
- Merge FGT-20C-ADSL and FWF-20C-ADSL
- Log Viewer Improvements
- Add AeroScout Inter-operabiliy testing
- Add "Last connection time" Column in FortiView > VPN
- FSSO agent support OU in group filters
- Certificate GUI improvements
- Improvement to WAN optimization feature
- Add FortiAP LED dark support
- Allow user to change VDOM operation mode more easily
- Support 4x10G interfaces in 5001D 40G ports
- Allow admin user to start/defer file system check if FGT was not shutdown properly
- Cloud Sandboxing
- Add a tooltip to remind users to activate FortiCloud to enable FortiSandbox cloud
- Add warn about factory default certificate
- Deep Flow

Interfaces on some FortiGate models are set in one-arm sniffer mode by default

Fort example:

- By default the FortiGate-300D port4 and port8 interfaces are in sniffer mode.
- By default the FortiGate-500D port5, port6, port13, and port14 interfaces are in sniffer mode.
- Other models may have similar default settings.

If you want to use these interfaces for other purposes you can change their mode from the GUI or CLI. From the GUI just go to **System > Network > Interface**, edit the interface and change its addressing mode as required.

Merge FGT-20C-ADSL and FWF-20C-ADSL

Add `set wan enable` to set one of the switch port as WAN port. By default, there is no WAN port for FWF-20C-ADSL and FGT-20C-ADSL.

CLI changes

Add `set wan enable` command.

Syntax

```
config system global
   set wan [enable|disable] //disable by default
end
```

This CLI command enables one of the switch port (LAN4 for 20C-ADSL) as wan port. In this way, a redundant WAN port is supported besides ADSL port.

By setting LAN4 into a switch port (set wan disable) or a dedicated WAN port (set wan enable), the two platforms can work in two modes:

1. ADSL + LAN (LAN1,LAN2,LAN3,LAN4 as one switch)
2. ADSL + LAN (LAN1,LAN2,LAN3 as one switch) plus WAN interface. Please note that:

- The option to switch between the two modes can be CLI-only.
- When switching between the 2 modes, a reboot is expected.
- `Set wan disable` won't take effect if WAN interface is in use.

Log Viewer Improvements

Extends Faceted Search portion of FortiView to support complicated sorting.

Improves usability of log viewer bottom pane with flexbox and css animations.

Allows filtering of combined column's constituent parts.

GUI changes

Replaced column filter icon on header with faceted search bar. Bottom panel now behaves better and resizes smoothly.

Add AeroScout Inter-operabiliy testing

Syntax

```
config wireless-controller wtp-profile
   edit <wtp-profile>
      config lbs
         set aeroscount Enable/disable
         set aeroscout-server-ip xxx.xxx.xxx.xxx // IP address of AeroScout server.
         set aeroscout-server-port <integer> // AeroScout server UDP listening port (1024 65535)
         set aeroscout-mu-factor <integer> // AeroScout dilution factor for Mobile Unit (MU) mode (default
             = 20)
         set aeroscout-mu-timeout <integer> // AeroScout dilution timeout (sec) for Mobile Unit (MU) mode
             (default = 5s)
      end
   next
end
```

Add "Last connection time" Column in FortiView > VPN

Users can sort by number of connections, duration and total bytes but cannot see the last time the user connected.

GUI changes

A ***Last connection time*** column has been added which can simply indicate the timestamps of the last VPN connection that was started for that user.

The user should be able to sort by ***last connection time***.

FSSO agent support OU in group filters

Previously, in FSSO configuration GUI page, via LDAP browser, admin can select user/group filters to send to FSSO Agent. Now that FSSO Agent supports OU filter. So GUI is updated to allow admin to select OU from LDAP browser.

GUI Changes

When creating FSSO group from Users/Groups creation wizard, in the LDAP browser, there is a new tab named ***Organizational Unit*** next to Users and Groups tab. This new tab can also be seen in FSSO dialog.

Certificate GUI improvements

Some GUI changes include:

- The table, under ***System > Certificates*** fit in one regular browser width by default, similar to ***Policy***, ***Interface*** and other pages.
- Wrap the text in the cells to keep the columns narrower.
- Improve the columns displayed to include:
  - Who signed it (where applicable).
  - Expiry date.
- Do not list certificates that do not exist on the FortiGate.

Improvement to WAN optimization feature

In some models WAN Optimization configuration can now be done from the CLI, you can still do GUI configuration after enabling GUI configuration from the CLI using following command:

```
config system global
   set gui-wanopt-cache enable
end
```

For more information, refer to the 5.2.3 feature/platform matrix at the following link:

http://docs.fortinet.com/d/fortigate-fortios-5.2.3-feature-platform-matrix

Add FortiAP LED dark support

Few customers want to keep their APs as discrete as possible, and want an option to run dark by turning off all LEDs.

Syntax

```
config wireless-controller wtp-profile
   edit "profile"
      set led-state enable|disable
   end
```

```
end
```

By default, led-state is set to enable.

FortiAP side:

```
cfg -a LED_STATE=0|1|2
```

0:LED is on, 1:LED is off, 2: LED is controlled by the controller (FortiGate).

By default, `LED_STATE` is set to 2. If it is set to 2, FortiAP will take `led-state` setting configured on the controller. If it is set to 0 or 1, FortiAP will ignore `led-state` setting configured on the controller.

Allow user to change VDOM operation mode more easily

Allow user to switch between NAT and TP mode without having to manually remove a large selection of configuration, this can be achieved using CLI and GUI.

Split 40G ports on some FortiGate models

On FortiGate models with 40G interfaces, such as the FortiGate-5001D and 3700D you can now split a single 40G interface into four 10G interfaces. Enabling split ports adjusts NP6 mapping.

Enter the following command to enable split ports for port1 and port2:

```
config system global
   set split-port port1 port2
end
```

When you enter this command the FortiGate reboots and when it starts up the ports are split. The GUI and CLI would show these split ports as port1/1, port1/2, port1/3, ... port2/4.

Allow admin user to start/defer file system check if FGT was not shutdown properly

When FGT wasn't shutdown properly, we don't start the file system check yet as it may takes time. Instead, after admin user logins, a dialog is shown offering admin user to start file system check or defer later. If file system check is chosen, FGT will be rebooted and file system check is started.

Cloud Sandboxing

FortiStandbox Settings is accessible under ***System > Config > FortiSandbox***, a new ***FortiSandbox Cloud*** option is available. When selected, it uses ***FortiCloud Account*** configured previously in the ***License Information*** widget.

Add a tooltip to remind users to activate FortiCloud to enable FortiSandbox cloud

FortiSandbox Cloud option is grayed out on the FortiSandbox settings page if FortiCloud account is not activated. Added a tooltip to remind users to activate FortiCloud to enable FortiSandbox cloud, also added a tool help element beside the FortiSandbox input that contains a helpful tips on how to enable FortiSandbox.

Add warn about factory default certificate

Default SSL-VPN server certificate has been changed from self-signed certificate to Fortinet_Factory certificate. When SSL-VPN is configured with a default certificate, show a warning on both the SSL-VPN settings dialog and

the policy dialog, recommending the use a proper signed certificate for better security.

Deep Flow

This new inspection mode uses IPS scan similar to Flow mode to catch anything obvious covered by signatures, but passing a copy of anything over 64 bytes to the scanunit engine to collect the parts of the payload for proxy style analysis, while the chunks of payload are sent to the recipient just as if it were in flow mode.

Once the last chunk of the payload is received by the scanunit engine, it is analyzed. If it successfully passes analysis the last chunk is sent off to the recipient.

This method is characterized as being as secure and effective as proxy mode but faster then regular Flow mode.

When configuring Deep Flow, GUI and CLI shows this option as Flow but the functionality as described earlier.

New features in FortiOS 5.2.2

This chapter provides a brief introduction to the following features that were added to FortiOS 5.2.2. See the release notes for a complete list of new features/resolved issues in this release.

- Add allocator API and counters to scanunit
- Add tooltips for application categories
- Add broadcast/multicast suppression for local bridge mode ssid on the FAP side
- Add hardware switch feature and SPAN functionality to 30D, 60, and 90D. Move POE ports out of Internal switch to independent interfaces
- Disable performance statistics Logging
- Improvements to firmware upload GUI dialog
- Reimplementation of the session list as a part of FortiView to improve functionality and usability
- Add GUI option to control the TLS versions for web administration
- Cloud Wifi Support
- Merge FWF/FGT-60D-3G4G and FGR-60D
- Add FAP-224D/222C/25D/214B/21D/24D/112D/223C/321C support
- Add support for more than 32k FortiClient configuration distribution through EC-NAC
- Add a warning when using deep SSL inspection mode on security policy and SSL profile pages
- Improve FSSO group GUI
- Add Log Rate stats to System Resources widget
- Add a command to export logs on local disk to external USB
- Improve FortiView performance and add System Events, Admin Logins, and VPN
- Integrate vmtools for FortiGate VMWare platforms

Add allocator API and counters to scanunit

Add a new memory management wrapper and statistics framework for scanunit to improve memory accounting.

CLI changes

Add diagnose sys scanunit stats command.

Syntax

```
diagnose sys scanunit stats <option>
```

Option	Description
list	List all statistics.
all	List all statistics.
clear	Clear all statistics.

Add diagnose sys scanunit filter command.

Syntax

```
diagnose sys scanunit filter <option>
```

Option	Description
list	Display the current filter.
clear	Clear the current filter.
negate	Negate the specified filter parameter.
vd	Index of virtual domain. -1 matches all.
worker	Index of worker. -1 matches all.

Add diagnose sys scanunit log filter command.

Syntax

```
diagnose sys scanunit log filter <option>
```

Option	Description
list	Display the current scanunit log filter.
clear	Clear the current scanunit log filter.
negate	Negate the specified filter parameter.
vd	Index of virtual domain. -1 matches all.
worker	Index of worker. -1 matches all.

Add diagnose sys scanunit restart command.

Syntax

```
diagnose sys scanunit restart
```

Add tooltips for application categories

Implementation of a tool tip for application category which are available in ***FortiView > applications*** ,and under ***Log & Report > traffic log***. For known categories, it provides a short description for the application category - this comes from FortiGuard app categories description. For unknown categories, the traffic has been scanned but the traffic pattern does not match any signature.

Add broadcast/multicast suppression for local bridge mode ssid on the FAP side

CLI changes

Add broadcast/multicast suppression for different packet type.

Syntax

```
conf wireless-controller vap
   edit <vap_name>
   set broadcast-suppression <option>
end
```

Option	Description
dhcp-up	Suppress broadcast uplink DHCP messages.
dhcp-down	Suppress broadcast downlink DHCP messages.
arp-known	Suppress broadcast ARP for known wireless clients.
arp-unknown	Suppress broadcast ARP for unknown wireless clients.
arp-reply	Suppress broadcast ARP reply from wireless clients.
netbios-ns	Suppress NetBIOS name services packets with UDP port 137.
netbios-ds	Suppress NetBIOS datagram services packets with UDP port 138.
ipv6	Suppress IPv6 packets.

Add hardware switch feature and SPAN functionality to 30D, 60, and 90D. Move POE ports out of Internal switch to independent interfaces.

Added virtual switch commands.

Syntax

```
config system virtual-switch
   edit lan
      set physical-switch sw0
         config port
            edit port1
            next
            edit port2
            next
         end
   next
end
```

Disable performance statistics Logging

A new CLI option `sys-perf-log-interval` was added into `config system global` section

Syntax

```
config system global
   set sys-perf-log-interval <value>
end
```

`value` is performance statistics logging interval (1 - 15 min, 0 = disable).

The default value of `sys-perf-log-interval` attribute is 5 minutes.

This attribute only affects the log to FortiAnalyser and/or Syslog, no `perf-stats` log goes to disk or FortiCloud no matter what the value is.

Improvements to firmware upload GUI dialog

A few items to consider for firmware upgrades:

- Maintain the upgrade path on FortiGuard with recommended version information.
- Allow user to easily upgrade to the recommended version.
- Show progress of downloading the image and upgrading, shows progress bar.

GUI changes

On the status page if a new update is available on the FortiGuard server then the next recommended update is displayed.

The admin can click the upgrade link and optionally backup the config before confirming the upgrade.

The dialog can display the progress of the update. Once the update is being installed the browser should probe the FortiGate until it has completed the reboot, then automatically refresh the browser to go to the login screen.

Similarly when going to the upgrade page if the user chooses to upgrade from the FortiGuard Network then the recommended firmware is set in the firmware version box (if any). If no firmware is recommended then "up to date" can be displayed. Note that there may be several firmware options available but he chooser should be set to the recommended version automatically, not just the latest version available. This information should be obtained from the upgrade path package from FortiGuard.

Once the update is complete and reboot starts the browser should try to probe the FortiGate until to responds then redirect to the login page once it is available again.

Reimplementation of the session list as a part of FortiView to improve functionality and usability

New options has been added to enable/disable inclusion of unscanned traffic in FortiView application charts and to enable/disable inclusion of local traffic in FortiView real-time charts.

Remove top sessions dashboard widget.

Syntax

```
config log gui-display
   set fortiview-unscanned-apps enable/disable // inclusion of unscanned traffic in FortiView application
       charts.
   fortiview-local-traffic enable/disable // inclusion of local-in traffic in FortiView realtime charts.
end
```

Add GUI option to control the TLS versions for web administration

Introduce GUI settings to allow admin control the TLS v1.x versions for GUI HTTPS..

Syntax

```
config system global
   set gui-https-tls-version <option>
end
```

Option	Description
tlsv1-0	TLS 1.0.
tlsv1-1	TLS 1.1.
tlsv1-2	TLS 1.2.

Cloud Wifi Support

FortiCloud customer account ID can be specified.

Syntax

```
config wireless-controller setting
   set account-id <string>
end
```

Merge FWF/FGT-60D-3G4G and FGR-60D

Moved `lte modem` command from `system global` to `system lte-modem`, and added `APN, authentication, redundant, extra-init, network type` commands.

CLI changes

Syntax

```
config system lte-modem
   set status enable/disable
   set extra-init STRING
   set authtype none/pap/chap
   set APN STRING
   set mode standalone/redundant
   set net-type CDMA-1x/EV-DO/LTE/Auto //Only available for F*60DC, since the feature only works for Novatel e362 module right now.
   set holddown-timer sec
end
```

Added `diagnose sys lte-modem` command

Syntax

```
diagnose sys lte-modem info
```

Sample output

```
LTE Modem configuration enabled!
LTE Modem device initialized.
Manufacturer: Novatel Wireless Incorporated
Model: E362 WWAN
MEID: 99000094761891
USB Modem Interface: up
SIM State: Valid
ICCID: 89148000000229083036
Signal Strength: 3
Network Type: LTE
Network Cfg: Automatic
APN: vzwinternet
Authen Type: none
Extra Init String:
Interface mode: standalone
Holddown Time: 30
```

GUI changes

GUI is almost the same, the difference is, when LTE Modem is plugged in but not connected, the same info items(vendor/model/iccid/meid etc) are still displayed, this gives more information to users.

Add FAP-224D/222C/25D/214B/21D/24D/112D/223C/321C support

CLI changes

Syntax

```
config wireless-controller wtp-profile
   edit <profile_name>
      config platform
      set type
```

```
        .....
        25D FAP25D
        222C FAP222C
        224D FAP224D
        214B FK214B
        21D FAP21D
        24D FAP24D
        112D FAP112D
        223C FAP223C
        321C FAP321C
    end
end
```

GUI changes

New platform FAP-224D/222C/25D/214B/21D/24D/112D/223C/321C can be selected in wtp profiles.

Add support for more than 32k FortiClient configuration distribution through EC-NAC

A new child table has been added to store advanced configuration greater than 32k

Syntax

```
config endpoint-control profile
   edit <profile_name>
      config forticlient-winmac-settings
         config extra-buffer-entries
            edit entry_id
            set buffer <string>
            next
         end
      end
   next
end
```

Add a warning when using deep SSL inspection mode on security policy and SSL profile pages

A help text has been added when enabling SSL deep inspection.

GUI changes

Add an information bubble on the firewall policy page, as well as in the SSL profile page when enabling or selecting deep inspection.

Add a video link via videos menu to both of the above pages to link to a new video that instructs users how to install these certificates throughout the network.

Improve FSSO group GUI

Apply new LDAP Browser to FSSO GUI pages allowing creating and updating FSSO group from the firewall policy page.

GUI changes

In the firewall policy edit dialog, clicking on the ***Create Users/Groups*** button on the bottom of the ***Source User (s***) drop-down list will launch the Wizard.

This is an extended version of the ***Users/Groups Creation Wizard*** which has extra option to create FSSO group. Clicking on ***FSSO*** will show the process of creating and/or updating FSSO group.

This new LDAP browser design has been applied to the ***Single Sign-On*** edit page.

Add Log Rate stats to System Resources widget

Log rate of disk and FortiAnalyser are shown in the ***System Resources*** widget when they were enabled.

Add a command to export logs on local disk to external USB

CLI changes

Add a command to backup all log files to USB drive.

Syntax

```
execute backup disk alllogs usb
```

Add a command to backup specific log file(s) to USB drive.

Syntax

```
execute backup disk log usb <string> //Choose log: traffic, event, ips, virus, webfilter, spam, dlp, voip, app-ctrl, anomaly, netscan
```

Improve FortiView performance and add System Events, Admin Logins, and VPN

GUI changes

Three new menu items has been added under ***FortiView***

- ***System Events***
- ***Admin Logins***
- ***VPN***

Integrate vmtools for FortiGate VMWare platforms

Open-vm-tools project is used as basis for new daemon.

CLI changes

Add a command to debug vmtools.

Syntax

```
diagnose debug application vmtools <integer>
```

New features in FortiOS 5.2.1

This chapter provides a brief introduction to the following features that were added to FortiOS 5.2.1. See the release notes for a complete list of new features/resolved issues in this release.

- Include bandwidth and setup rate statistics in the event log
- Allow export of collected emails
- Ssl-ssh-profile is no longer mandatory when utm profiles are enabled
- Disallow multiple destination interfaces on an IPsec firewall policy
- Add a new diag test command for fnbamd
- Add deregister all option in diagnose endpoint control registration
- Redirect kernel messages to non-console terminals
- Add FortiExtender supported 3G/4G modem list
- Add a new option for STP forwarding
- Suppress probe response based on threshold in wireless controller vap
- Move global antivirus service settings into profile-protocol-options
- Add Ekahau Blink Protocol support and reorganization for station-locate
- Implement diagnose command to test flash SSD
- Online help improvements
- Add iprope check trace in flow trace
- Log id-fields reference improvements
- Add diagnose debug admin error-log command
- Improve hasync debug
- Improve interface list and switch mode
- Wizard improvement
- Allow VIP with port forwarding to permit ICMP
- Support captive portal for block notification page
- Add diagnose log clear-kernel-state command
- Apply new LDAP Tree Browser design to the User Wizard and User Group page
- New Join and try requests to FortiCloud for low-end models

Include bandwidth and setup rate statistics in the event log

Bandwidth and setup rate statistics are vital for customer's units health reports.

The advantage of these parameters are:

- Improves performance on FAZ. Simple query small logs makes FAZ build reports faster and have more idle time for other reports.
- Reduces amount of logs send to FAZ.
- Uses less disk space on FAZ for the same report type.

Allow export of collected emails

This feature adds a new monitor page called **Collected Email Addresses** under **User & Device > Monitor** menu, it is essentially a filter on the device list for devices that have an email address associated with them.

The feature allows the administrator to export the list to a CSV file which can then be used for marketing or analysis purposes.

Ssl-ssh-profile is no longer mandatory when utm profiles are enabled

When UTM profiles are enabled in a security policy, you can set or unset `ssl-ssh profile`.

Syntax

```
config firewall policy
   edit 1
      set ssl-ssh profile <test>
   next
end
```

Disallow multiple destination interfaces on an IPsec firewall policy

When a firewall policy is set to action **IPsec**, multiple **Outgoing Interface** should not be allowed.

Since multiple destination interfaces on an IPsec policy aren't necessary, the CLI and GUI was updated to explicitly disallow it.

Add a new diag test command for fnbamd

The following command was added to show authentication session statistics:

Syntax

```
diagnose test application fnbamd 1
```

Sample output

```
diagnose test application fnbamd 1
Pending sessions:      0
Max session reached:   0
Auth:
   requests:         5000
   sessions:         5000
   released:         5000
Acct:
   requests:         74
   sessions:         0
   released:         0
Cert:
   requests:         0
   sessions:         0
   released:         0
```

Add deregister all option in diagnose endpoint control registration

When there is a long list of registered endpoint needed to be deregistered, the following command was added to do so:

```
diagnose endpoint registration deregister all
```

Redirect kernel messages to non-console terminals

To be able to see kernel messages from ssh or telnet which needed when customer unit is accessible remotely, the following command has been added:

```
diagnose debug application kmiglogd <Integer>
```

`<Integer>` is the debug level. For example, 1 would be the maximum log level in kernel to be shown.

Add FortiExtender supported 3G/4G modem list

A new 3G/4G modem list is introduced that contain the list of supported modems for both FortiGate and FortiExtender.

GUI changes

Under the **System > Network > Modem** page, click **Configure Modem** link under the **External Modem** section to see the list for FortiGate and FortiExtender.

Under the **System > Network > FortiExtender** page, click **Configure Settings** and click **Supported Modems** link under **Modem Settings** section to show the supported FortiExtender modem list. This will jump back to the page under **System > Network > Modem** page, click **Configure Modem** link.

Syntax

The following new diagnose command was added to show the list of supported FortiExtender modems:

```
diagnose extender modem-list
```

Add a new option for STP forwarding

Due to STP forwarding problem in one-arm transparent mode firewall, a new option: replace nothing (`rpl-nothing`) has been added when configuring `stpforward-mode`.

Syntax

```
config system interface
   edit wan1
      set stpforward enable
      set stpforward-mode rpl-nothing
   next
end
```

Suppress probe response based on threshold in wireless controller vap

The wireless controller vap supports probe response suppression (probe-resp-suppression) and probe response threshold (probe-resp-threshold).

Syntax

```
config wireless-controller vap
   edit "SSID"
      set probe-resp-suppression enable|disable
      set probe-resp-threshold <value>
   next
end
```

probe-resp-threshold range is [-20,-95]dBm, and the default is -80dBm if enabled.

Move global antivirus service settings into profile-protocol-options

The global antivirus service settings moved into profile-protocol-options (options included: uncompsizelimit, uncompnestlimit, scan-bzip2, and block-page-status-code). HTTP and HTTPS combined into HTTP, uncompsizelimit changed to uncompressed-oversize-limit and uncompnestlimit to uncompressed-nest-limit. scan-bzip2 set to enabled by default and an appropriate help text added.

On upgrade, the options from antivirus service are moved into the corresponding entries in each profile-protocol-options.

CLI changes

The following options are moved from global antivirus service to firewall profile-protocol-options: uncompsizelimit, uncompnestlimit, scan-bzip2, and block-page-status-code moved.

The following options are removed: ftp, ftps, http, https, imap, imaps, nntp, pop3, pop3s, smtp, and smtps.

The following help test was added:

uncompressed-oversize-limit Maximum in-memory uncompressed size that can be scanned.

uncompressed-nest-limit Maximum uncompress nest level that can be scanned.

scan-bzip2 Enable/disable scanning of BZip2 compressed files.

block-page-status-code Return code of blocked HTTP pages (non-FortiGuard only).

Add Ekahau Blink Protocol support and reorganization for station-locate

We used to have a config command to report station position for retail analytic server under config wireless-controller wtp-profile > radio > station-locate. A new feature ekahua-blink-mode has been added.

These features are all location based service (LBS) related and they moved to a sub-config under wtp-profile, and they are per wtp-profile configuration.

On upgrade, the options from antivirus service are moved into the corresponding entries in each profile-protocol-options.

Syntax

```
config wireless-controller wtp-profile
   edit <wtp-profile-name>
      config lbs
         set ekahau-blink-mode Enable/disable
         set ekahau-tag <xx:xx:xx:xx:xx:xx>
         set erc-server-ip <any_ip>
         set erc-server-port <integer>
      end
end
```

`<xx:xx:xx:xx:xx:xx>` mac address.

`<any_ip>` Any ip xxx.xxx.xxx.xxx.

`<integer>` input integer value.

Implement diagnose command to test flash SSD

A new diagnose command has been implemented to test the disk.

Syntax

```
diagnose disktest <option>
```

Option can be the following:

`device` Specify which device to test.

`block` The block size of each read/write operation.

`time` The limit of test time of each cycles. Default is no limit.

`size` The limit of test size of each cycles. Default is no limit.

`run` Run test with specified cycles. Default is infinite cycles.

Online help improvements

A video links to some help topics has been added in the FortiOS GUI header bar.

Add iprope check trace in flow trace

Previously flow trace shows only accepted or denied policy information. Sometimes, policy tracking is also important and knowing which policies are checked, and what is the result for the checking might be helpful.

Syntax

```
diagnose debug flow show iprope {enable|disable}
```

`enable` to enable trace iprope match.
`disable` to disable trace iprope match.

Log id-fields reference improvements

This improvement is to make a complete reference for each log id with its corresponding fields in FortiOS.

CLI changes

Add new `endpoint` and `ha` subcategories into `config log eventfilter`

Syntax

```
config log eventfilter
   set endpoint Enable/disable
   set ha Enable/disable
end
```

GUI changes

Add subtype log filter options named **Endpoint** and **HA** under **Event Log**

Add diagnose debug admin error-log command

Since the last failed admin login is recorded, this new command shows details about the failed admin login attempt.

Syntax

```
diagnose debug admin error-log
```

Sample output

```
The recent admin user failed login details:
error code       :       -100
method           :       ssh
login name       :       test
cmdb name        :       null
login vdom       :       root
current vdom     :       root
override vdom    :       null
login profile    :       null
override profile :       null
login time       :      2014-08-29 11:01:57
```

Improve hasync debug

Add diag test application hasync to control hasync debug finely.

Syntax

```
diag test application hasync [1-19,50-53]
```

Value	Description
1	Dump all states of debug switches.
2	Turn off all debug switches.
3	Toggle debug switch of hsync core.
4	Toggle debug switch of ha-diff.
5	Toggle debug switch of FIB.
6	Toggle debug switch of route6.
7	Toggle debug switch of BYOD.
8	Toggle debug switch of endpoint_compliance.
9	Toggle debug switch of NEB.
10	Toggle debug switch of zebos.
11	Toggle debug switch of haconf.
12	Toggle debug switch of proxy.
13	Toggle debug switch of time.
14	Toggle debug switch of snmp.
15	Toggle debug switch of gtp.
16	Toggle debug switch of auth.
17	Toggle debug switch of IPsec.
18	Toggle debug switch of fdb.
19	Toggle debug switch of arp.
50	Dump ha sync statistics.
51	Dump FIB information.
52	Dump extfile's signature.
53	Recalculate external files signature.

Improve interface list and switch mode

This features introduces grouping interfaces by interface type and adds switch to toggle between **VLAN Switch Mode** and regular **Hardware Switch Mode**.

GUI changes

- A **Group By Type** toggle switch has been added in the **interfaces** page under **System > Network > Interfaces**.
- A **VLAN Switch Mode** toggle switch has been added in the **interfaces** page under **System > Network > Interfaces**. This **VLAN Switch Mode** toggle switch shows a confirmation dialog when clicked before toggling the system setting.
- A mini faceplate for **Hardware Switch Mode** and **VLAN Switch Mode** has been added in the **member** column under **System > Network > Interfaces**.

Wizard improvement

The Wizard has been improved to provide instruction page to explain how to set up FortiClient for IPsec and SSLVPN and permit to set up FortiCloud connection on Wizard so that logs will be sent to FortiCloud.

GUI changes

- Add instruction module to generate page explaining how to set up FortiClient for IPsec and SSLVPN depending on the VPN that is configured.
- Add a Wizard Summary Page.
- Allow FortiOS Setup wizard to set up FortiCloud.

Allow VIP with port forwarding to permit ICMP

When a VIP is defined with port forwarding enabled, ICMP (PING) to the mapped IP can be allowed.

Syntax

```
config firewall vip
   edit "VIP"
      set extip xxx.xxx.xxx.xxx
      set extintf "wan1"
      set portforward enable
      set mappedip xxx.xxx.xxx.xxx
      set protocol icmp
   next
end
```

The command `set protocol` has `icmp` option now to make the firewall forward ICMP to the host specified by `mappedip` while the `mappedport` and `extport` attributes are skipped.

Support captive portal for block notification page

The main requirement of this feature is to present a block notification page if the web access is denied by a firewall policy.

Add diagnose log clear-kernel-state command

This command has been added to clear log statistics in kernel in order to improve disk log session setup rate.

Syntax

```
diagnose log clear-kernel-stats
```

Apply new LDAP Tree Browser design to the User Wizard and User Group page

Previously, the LDAP browser shows LDAP containers and LDAP entries within the same tree. When there are many LDAP entries available, it becomes harder for users to select, filter, search different types of LDAP objects.

This new feature now divides the LDAP Browser into two major parts:

- A tree to show the container.
- Tables to show different type of LDAP object entries.

New Join and try requests to FortiCloud for low-end models

These new `join` and `try` requests are for low-end models only such as: FG-30D, FWF-30D, FG-60D, FWF-60D, FG-70D, FG-80D, FG-90D, and FWF-90D.

Syntax

```
exec fortiguard-log join
exec fortiguard-log try <FortiCloud_id> <Password>
```

Top Features

This chapter introduces the following top features of FortiOS 5.2:

- Unified Policy Management
- FortiView Dashboards
- SSL Inspection
- Web Filtering
- Application Control
- IPsec VPN Creation Wizard
- Captive Portal
- FortiAP Management
- Flow-based Antivirus
- FortiExtender Support
- Using a Virtual WAN Link for Redundant Internet Connections
- Internet Key Exchange (IKE)
- SSL VPN Creation
- On-Net Status for FortiClient Devices

Unified Policy Management

The different creation pages in the web-based manager for policy types and subtypes (user-identity, device identity, and VPN) have been merged into a single main policy creation page. New fields have been added for **Source User(s)** and **Source Device Type** that remove the need for multiple authentication rules in a single policy. This allows for greater control and customization of policies, as a combination of these source types can be used in a single policy rather than having to pick one type.

For more information, see Unified Policy Management on page 103.

FortiView Dashboards

The **FortiView** dashboards integrate real time and historical dashboards into a single view that displays the top 100 sessions on a FortiGate unit. The different dashboards show information on the following:

- Sources
- Applications
- Cloud applications
- Destinations
- Web sites
- Threats
- All sessions

For more information, see "Usability Enhancements" on page 92.

SSL Inspection

Several changes have been made to how SSL inspection is handled by a FortiGate unit, with the addition of a new mode that allowed HTTPS traffic to be scanned without enabling deep inspection, as well as changes to the handling of certificates and configuring exemptions for SSL inspection.

For more information, see SSL Inspection on page 114.

Web Filtering

Several new options have been added for web filtering:

- Restricting Google access to specific domains
- New protocols for warnings and authentication
- Modifying HTTP request headers
- Adding a referer to URL filters.
- Using FortiGuard rating checks for images, JavaScript, CSS, and CRL
- Additional replacement message variables

For more information, see Web Filtering on page 116.

Application Control

Several new options have been added for application control:

- Deep inspection for cloud applications
- Traffic shaping settings
- 5-Point-Risk Ratings
- Replacement messages
- Support for SPDY protocol

For more information, see "Security Profiles" on page 119.

IPsec VPN Creation Wizard

The IPsec VPN wizard is the only web-based manager tool for creating interface- or route-based IPsec VPNs. All it takes is a few steps with the wizard to create a wide variety of interface-based IPsec VPN configurations. In addition to the IPsec settings the wizard creates all required routes and policies.

In FortiOS 5.2, expanded options have been added to the wizard, allowing it to be used for more types of VPN configurations. Tunnel templates have been created for popular configurations.

For more information, see VPN Creation Wizard on page 124.

Captive Portal

Several new options have been added for captive portals:

- External captive portals
- Using groups from the security policy

- Exempting a policy
- Replacement messages
- New configuration options for wireless
- WPA personal security + captive portal for wireless

For more information, see Captive Portal on page 134 and Captive Portal for WiFi on page 142.

FortiAP Management

Several new options have been added for managing FortiAP units:

- Manually selecting AP profiles
- AP scanning
- Radio settings summary
- CLI console access
- Split tunneling for wireless traffic

For more information, see FortiAP Management on page 140.

Flow-based Antivirus

In FortiOS 5.2, flow-based AntiVirus has been improved to have the same enhanced performance as flow-based antivirus scanning in FortiOS 5.0 while providing the same accuracy and many of the extended features of proxy-based antivirus.

For more information, see Flow-based Antivirus on page 121.

FortiExtender Support

FortiOS 5.2 supports FortiExtender, that allows you to remotely connect 4G/LTE USB modems to a FortiGate unit. The FortiGate unit can remained installed in a secure location while the FortiExtender is installed on a roof or near a window providing enhanced 4G/LTE modem reception.

For more information, see FortiExtender Support on page 76.

Using a Virtual WAN Link for Redundant Internet Connections

A virtual WAN link consists of two or more interfaces that are connected to multiple ISPs. The FortiGate unit sees the virtual WAN link as a single interface so the FortiGate's security policy configuration no longer has be redundant to support dual Internet links. In addition, the virtual WAN link includes load balancing and new link health checking and settings.

For more information, see Using a Virtual WAN Link for Redundant Internet Connections on page 78.

Internet Key Exchange (IKE)

Several new options have been added for how IKE is supported on a FortiGate:

- Multiple interfaces
- Mode-configuration
- Certificates groups

- Authentication methods
- Inheriting groups from the security policy
- Assigning client IP addresses using the DHCP proxy
- Transform matching
- Cookie notification
- Message ID sync for High Availability

For more information, see Internet Key Exchange (IKE) on page 126.

SSL VPN Creation

SSL VPN configuration has been simplified with new settings and portal creation pages. Most SSL VPN settings can be configured on one web-based manager page, with additional settings handled as part of the security policy.

For more information, see SSL VPN Configuration on page 132.

On-Net Status for FortiClient Devices

A new status option, On-Net, has been added for FortiClient devices that show if that device has been registered with the FortiGate unit.

For more information, see On-Net Status for FortiClient Devices on page 138.

System Features

New system features include:

- FortiExtender Support
- Using a Virtual WAN Link for Redundant Internet Connections
- FortiGuard Services
- Netflow v9.0
- DHCP Server Configuration
- Improvements to Aggregate/Redundant Interfaces
- Link Layer Discovery Protocol
- CPU and Memory Usage per VDOM
- Custom Languages for Guest Management and SSL VPN Portals
- Packet Capture Options for Admin Profiles
- FortiCloud Modem List
- SPAN Support for Hard-Switch Interfaces
- Setting the Service and AC-name in PPOE PADI/PADO Negotiations
- Disabling FortiExplorer, the USB MGMT Port, and the Serial Console
- Port Kernel Profiling
- Using a Second Destination IP (VRDST)
- Session Rate Stats per VDOM
- Disable Honoring the Don't-Fragment Flag
- Disable Login Time Recording
- Per-IP-Bandwidth-Usage Feature Removed
- Modem Support

FortiExtender Support

FortiOS 5.2 supports the new FortiExtender unit, which provides internet connectivity via 4G/LTE network to a FortiGate unit.

To connect a FortiGate and FortiExtender, a new tap interface is created on the FortiGate unit, which receives the IP address from the cellular service provider via the FortiExtender, using a CAPWAP data channel. All the packets sent to the tap interface are received by the extender module on the FortiGate and are then sent to the FortiExtender, which then sends the packets out on the 4G/LTE network.

When data packets are received from the cellular network, the FortiExtender passes the packets to the FortiGate via the CAPWAP data channel. These packets are written to the tap interface and the FortiGate IP stack will process them.

The options to configure a FortiExtender unit can be found by going to **System > Network > FortiExtender**.

The configuration of a FortiExtender interface is restricted to the root VDOM.

Connecting a FortiExtender unit to a FortiGate unit

1. If you are using the provided PoE injector:
   a. Plug the provided Ethernet cable into the Ethernet port of the FortiExtender and insert the other end of the Ethernet cable into the AP/Bridge port on the injector, then plug the injector into an electrical outlet.
   b. Connect the LAN port of the PoE injector to a FortiGate, FortiWifi, or FortiSwitch device.
2. If you are not using the PoE injector, insert the other end of the Ethernet cable into a PoE LAN port on an appropriate FortiGate, FortiWiFi or FortiSwitch device.
3. By default, the options for the FortiExtender are hidden and disabled. Enable them in FortiGate's CLI:

```
config system global
   set fortiextender enable
   set wireless-controller enable
end
```

4. Enable the control and provisioning of Wireless Access Point (CAPWAP) service on the port to which the FortiExtender unit is connected (**lan** interface in this example) using the following CLI commands:

```
config system interface
   edit lan
      set allowaccess capwap
   end
end
```

Once enabled, it appears as a virtual WAN interface in the FortiGate, such as *fext-wan1*.

Configuring the FortiExtender unit

1. At this point, you can fully manage the FortiExtender from the FortiGate unit. To achieve this, you need to authorize the FortiExtender by going to **System > Network > FortiExtender** and click on **Authorize**. Once authorized, you can configure the following settings as required:
   - **Link Status**: Shows you if the link is **Up** or **Down**, click on **Details** to see the System and Modem Status.
   - **IP Address**: Shows you the current FortiExtender's IP address, click on the link of the IP address to connect to the FortiExtender GUI.
   - **OS Version:** Shows the current FortiExtender's build, click on **Upgrade** if you wish to upgrade the Firmware.
   - **Configure Settings**: Allows you to configure the Modem Settings (for more information, see below), PPP Authentication, General, GSM / LTE, and CDMA .
   - **Diagnostics**: Allows you to diagnose the FortiExtender unit, you can choose a command form the existing commands and click on **Run**. Existing commands are: `Show device info, Show data session connection status, test connection, test disconnection, Get signal strength, AT Command.`

The FortiExtender unit allows for two modes of operation for the modem; **On Demand** and **Always Connect**. In **On Demand** mode, the modem connects to a dialup ISP account to provide the connection to the Internet when needed. In **Always Connect** mode, the modem is always connected to the internet, it can acts as a primary or backup method of connecting to the Internet. To configure the dial mode as needed, do the following:

2. Select **Configure Settings**.
3. Extend **Modem Settings**.
4. Select the **Dial Mode** of **Always Connect** or **On Demand**.
5. Enter the **Quota Limit** to the desired limit in Mega Byte.
6. Select **OK**.

Configuring the FortiGate unit

1. Go to **Router > Static > Static Routes** or **System > Network > Routing**, depending on your FortiGate model, and select **Create New**.

If your network will be using IPv6 addresses, go to **Router > Static > Static Routes** or **System > Network > Routing** and select **IPv6 Route**.

2. Set the **Destination IP/Mask** to 0.0.0.0/0.0.0.0, **Device** to **fext-wan1**, and set the **Gateway** to your gateway IP or to the next hop router, depending on your network requirements.
3. Select **OK.**
4. Go to **Policy & Objects > Policy > IPv4** and select **Create New.**

If your network will be using IPv6 addresses, go to **Policy & Objects > Policy > IPv6** and select **Create New.**

5. Set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to **fext-wan1** interface. You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements.
6. Make sure the **Action** is set to **ACCEPT**. Turn on **NAT** and make sure **Use Destination Interface Address** is selected.
7. Select **OK.**

Using a Virtual WAN Link for Redundant Internet Connections

To make sure your network is always connected to the Internet you can engage the services of two or more Internet service providers and set up redundant Internet connections. Then, if one of your ISPs service is interrupted, all of your Internet traffic can be switched to the other ISP, maintaining your Internet connection. Also, while both ISPs are operating you can load balance traffic between them, increasing your network's available Internet bandwidth.

Previous versions of FortiOS required a few steps to set up two interfaces as redundant Internet connections. The setup also involved some special routing and load balancing setup and creating duplicate policy configurations for each Internet facing interface. In addition, previous versions of FortiOS supported basic link monitoring.

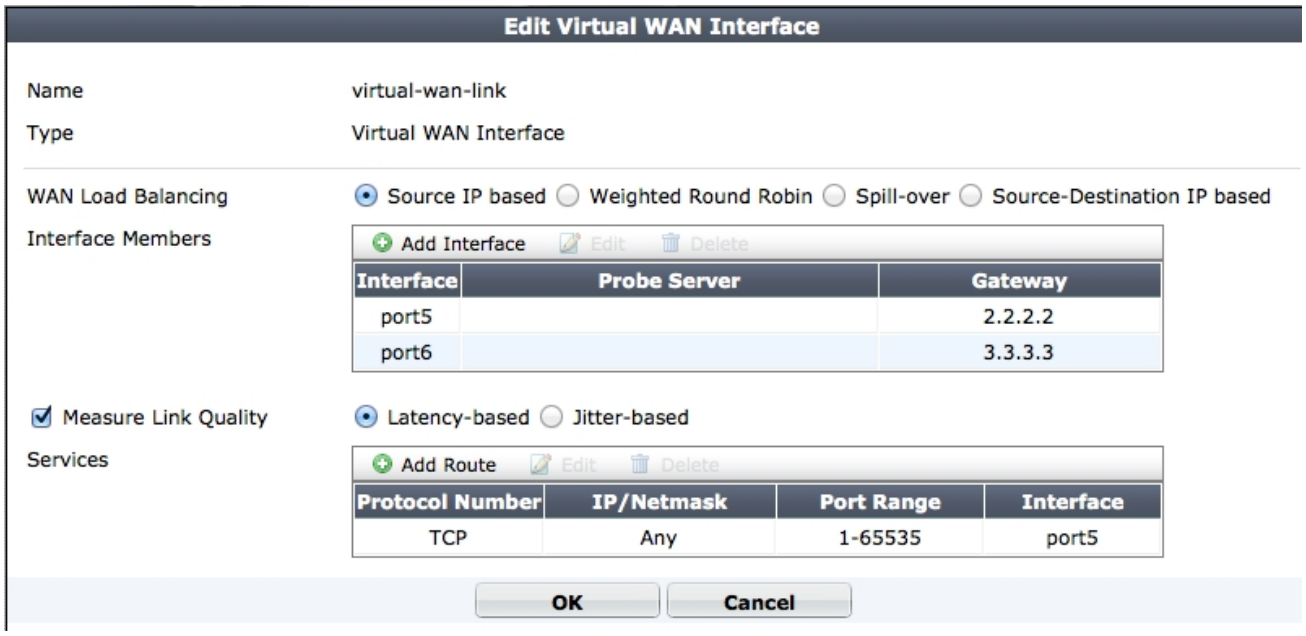
FortiOS 5.2 adds a new type of interface called a virtual WAN link. A virtual WAN link consists of two or more physical interfaces that are connected to two or more ISPs and to the Internet as well as the load balancing and routing configuration required to support redundant internet connections. In addition, the virtual WAN link configuration also includes new link health checking and settings to control traffic flow based on link health.

The FortiGate unit sees the virtual WAN link as a single interface so the FortiGate's security policy configuration no longer has be redundant to support dual Internet links. Now one policy configuration to control traffic to the virtual WAN link is all that is required. You can also add or remove redundant Internet links just by adding or removing physical interfaces from the virtual WAN link. No addition changes to the routing, load balancing or firewall policy configuration are required.

Setting Up a Virtual WAN Link

To set up a virtual WAN link, go to **System > Network > Interfaces** and select **Create New > Virtual WAN**. Add the interfaces connected to ISPs to the virtual WAN link. For each interface you must enter a gateway IP, usually provided by your ISP. You can also change load balancing settings (such as Spillover Threshold and Weight) and set up link health checking (called measuring link quality).

Virtual WAN link configuration



Once you have added interfaces to the virtual WAN interface you should go to **Router > Static > Static Route** and add a default route for the virtual WAN link. Then add firewall policies that allow access to the Internet by setting the outgoing interface to virtual-wan-link.

For more information about using a virtual WAN link, please see the FortiGate Cookbook recipe Redundant Internet connections (5.2.0) .

Setting Up Virtual WAN Link Load Balancing

By default when you set up a virtual WAN link source IP based load balancing is selected and traffic is load balanced among the interfaces added to virtual WAN link configuration. You can change the load balancing method to weighted load balancing, spill-over load balancing or source-destination IP load balancing. Selecting a different load balancing method may also require configuring the interfaces added to the virtual WAN link to add weights (for weighted load balancing) or to set spillover thresholds.

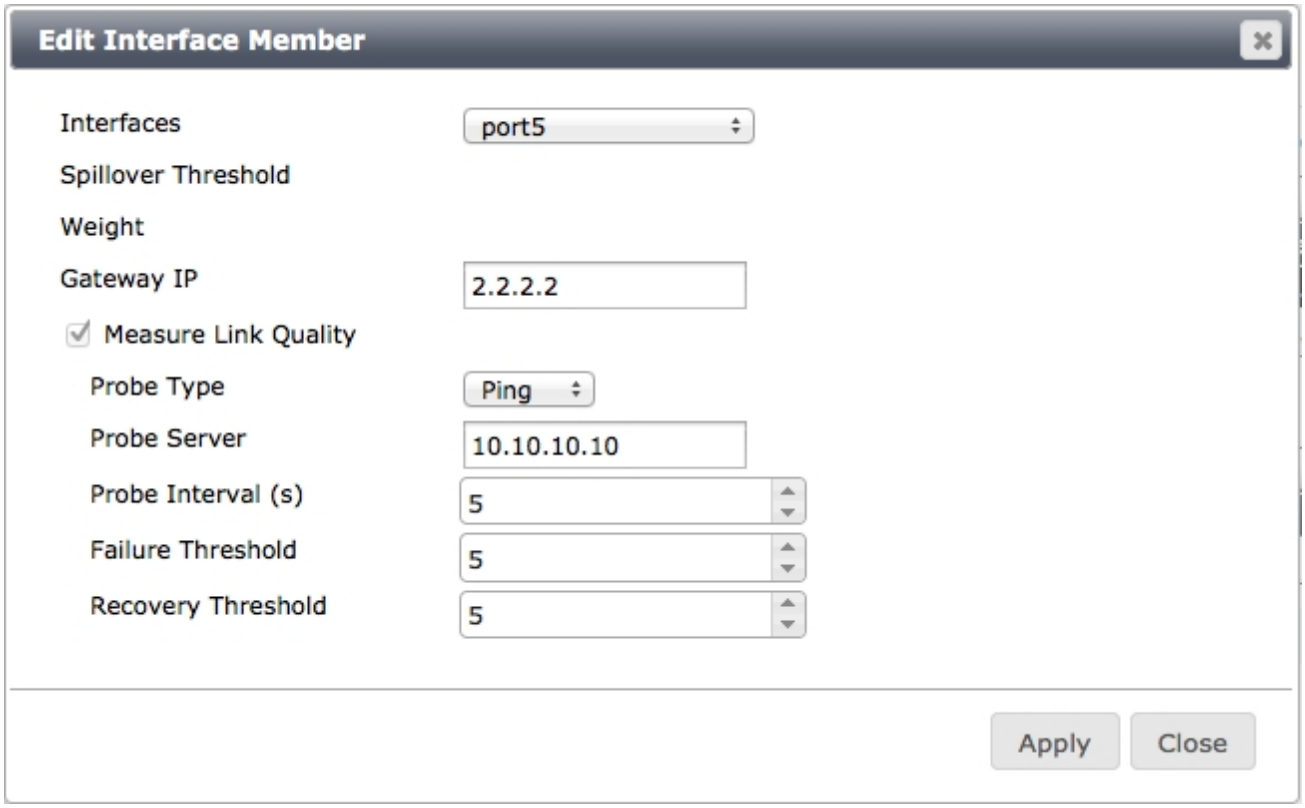
Directing Traffic to Higher Quality Links

You can configure link quality measuring (link health checking) on the interfaces added to the virtual WAN link. Depending on how you configure the virtual WAN link this link quality checking is based on latency or jitter. With link quality checking in place you can configure Services to control the links used for selected types of traffic. For example, media-based traffic like SIP is very sensitive to jitter. If you set up link quality checking to check for jitter,

you can configure the virtual WAN link to send SIP traffic to the link with the lowest jitter (and so the highest quality link).

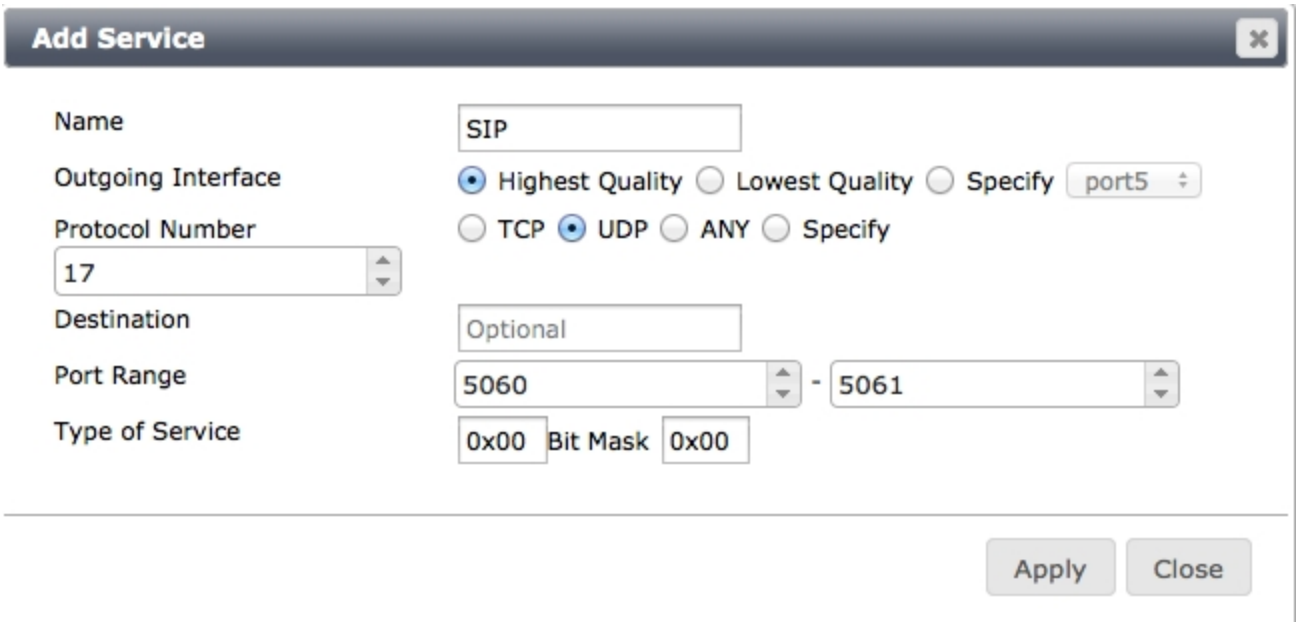
To configure link checking on individual interfaces added to a virtual WAN link, edit Interface members in the virtual WAN link, select Measure Link Quality and set the quality measurement options. You can measure link quality using ping or HTTP, select a server to communicate with to perform link quality checking and set the probe interval, failure threshold and recovery threshold.

Configuring link health checking



Next, add Services that control how traffic patterns are affected by link quality. Services work like policy routes. Configure a service by defining a traffic type (for example, SIP) and specifying whether this traffic always goes to the highest quality interface, the lowest quality interface or a specific interface no matter the quality.

Virtual WAN link service



Measured Volume Based Distribution

Your FortiGate can actively measure the volume of traffic sent to each WAN link and distribute new sessions to balance the traffic volume to each link using a simple ratio calculation. To use this feature, use the following CLI command:

```
config system virtual-wan-link
   set load-balance-mode measured-volume-based
   config member
      edit <ID>
         set volume-ratio <number>
      end
   end
end
```

The Link Monitor

You can monitor link health using the **Link** monitor, which can be found by going to **System > Monitor > Link Monitor**.

FortiGuard Services

Several changes have been made to how FortiGuard services can be received by your FortiGate unit.

FortiGuard Server List

In FortiOS 5.2, you can create a server list for receiving FortiGuard updates, allowing you to use different servers for different FortiGuard services. Each server can be used for either web filter and anti-spam ratings or AV/IPS signature updates.

The server list also has the ability to include the default servers by adding them to the end of the list. This option is only available if the central management type is not set to FortiGuard.

If no server list is configured, the FortiGuard will not use the public FortiGuard servers as resolved by DNS.

Syntax

```
config system central-management
   config server-list
      edit <ID>
         set server-type {rating | update}
         set server-address <address>
      end
   set include-default-servers {enable | disable}
end
```

Using TCP Port 80 to Receive Updates from a FortiManager Unit

Communications to a FortiManager unit in order to receive FortiGuard updates are now supported using TCP port 80.

To configure communications to use port 80, go to **System > Config > FortiGuard** and expand **Web Filtering and Email Filtering Options**. Select **Use Alternate Port (80)**. This can also be configured using the CLI.

Syntax

```
config system fortiguard
   set port 80
end
```

FortiGuard TCP stats can also be displayed using the `diagnose test application urlfilter 20` command.

Netflow v9.0

FortiOS 5.2 supports Netflow v9.0. NetFlow services provide network administrators with access to IP flow information from their data networks. Network elements (routers and switches) gather flow data and export it to collectors. The collected data provides fine-grained metering for highly flexible and detailed resource usage accounting.

A flow is defined as a unidirectional sequence of packets with some common properties that pass through a network device. These collected flows are exported to an external device, the NetFlow collector. Network flow records include details such as IP addresses, packet and byte counts, timestamps, application ports, and input and output interfaces.

Configuring the Global Settings for Netflow Collector and Timers

The global settings for Netflow can be configured in the CLI:

```
config system netflow
   set collector-ip <address>
   set collector-port <port>
   set source-ip <address>
   set active-flow-timeout <integer>
   set inactive-flow-timeout <integer>
end
```

The value for `active-flow-timeout` is used as the minimum length of a live session, as well as for the intervals to send the report. The default is 1 minute, meaning that if a session lives for a minute, it will be reported in a Netflow packet.

The value for `inactive-flow-timeout` is used as the interval to send a Netflow report of inactive (finished) flows. Since FortiOS uses 1350 Byte payloads, the number of reports in a packet are limited and multiple packets may be sent regardless of this timer.

Using Netflow with VDOMs

For VDOM environments, excluding the management VDOM, Netflow must be configured using the following CLI commands:

```
config system vdom-netflow
   set vdom-netflow enable
   set collector-ip <address>
   set collector-port <port>
   set source-ip <address>
end
```

Adding Netflow Sampling to an Interface

Netflow sampling can be enabled on an interface to sample transmitted traffic (tx), received traffic (rx), or both using the CLI:

```
config system interface
   edit <name>
      set netflow-sampler {disable | tx | rx | both}
   end
end
```

Viewing the Configuration

Netflow does not have a separate daemon and is instead running under sflowd. The current Netflow configuration can be viewed by using test level 3 or 4:

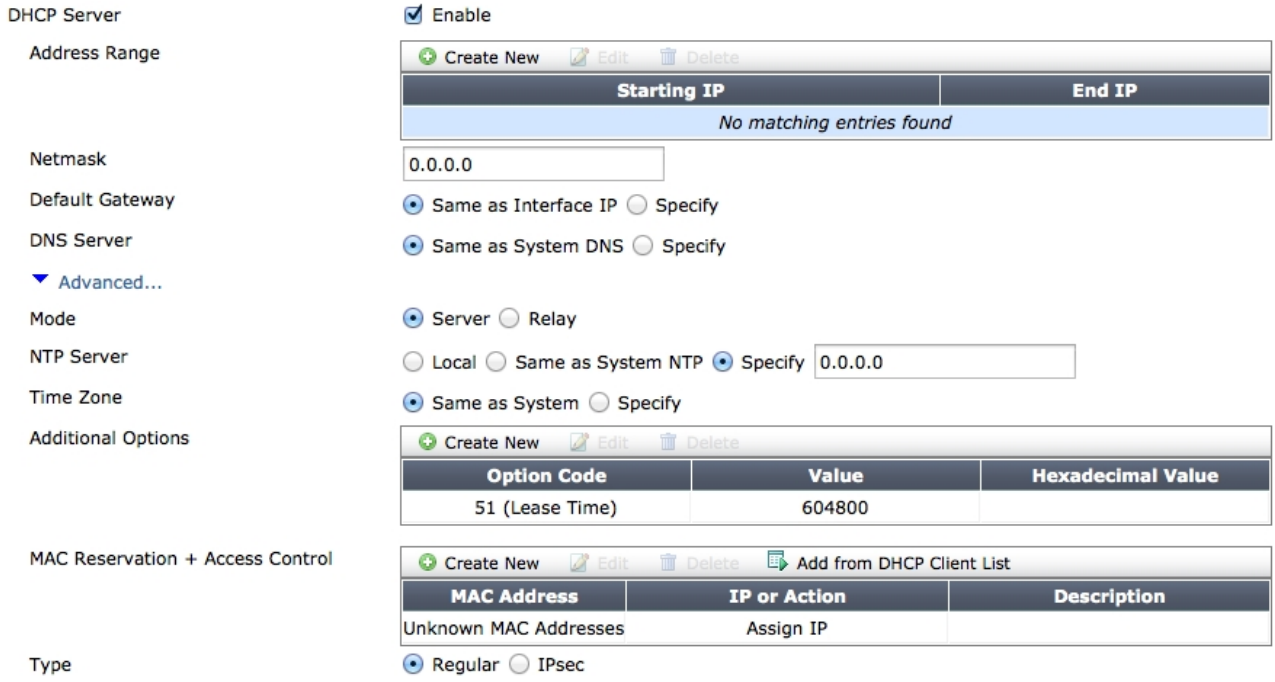
```
diagnose test application sflowd 3
diagnose test application sflowd 4
```

DHCP Server Configuration

The following attributes have been added for DHCP server configuration to both the web-based manager and the CLI:

- Time zone
- TFTP server
- TFTP filename

DCHP server settings



Syntax

```
config system dhcp server
   edit <integer>
      set timezone-option {disable | default | specify}
      set timezone <timezone_code>
      set tftp-server <string>
      set filename <file_name>
   end
end
```

Improvements to Aggregate/Redundant Interfaces

Several improvements have been made in FortiOS 5.2 for aggregate or redundant interfaces.

Minimum Number of Links in an Aggregation

You can now set a minimum number of links that must exist in an aggregation. If this number is not reached, the device will failover. The minimum links value can be set between 1-32, with 1 being the default value.

Aggregates can also now be configured so that they are taken down administratively when the min-links threshold is passed. This will cause all the members to be taken down administratively as well.

Syntax

```
config system interface
   edit <name>
      set type aggregate
      set vdom root
      set member <ports>
      set min-links <integer>
      set min-links-down administrative
   end
end
```

Avoiding Traffic Disturbances

Two new methods have been added to avoid traffic disturbances for an aggregate that can be caused by ports flapping up and down and being repeatedly added and removed from the aggregate.

Setting the Link Up Delay Period

When a member port in an aggregate/redundant becomes operationally up, be default it is considered as a viable port for aggregation/redundancy after 50ms. Increasing this delay can minimizing the effect of a flapping port by causing the FortiGate to wait longer before deciding if a port is considered viable. This option is available for both redundant and aggregate interfaces.

Syntax

```
config system interface
   edit <name>
      set type {aggregate | redundant}
      set link-up-delay <time>
   end
end
```

Enabling Priority Override

In the case of a redundant port, there is only one port actively carrying traffic thus the only time a port coming up can affect existing traffic is where the primary port went down, traffic moved to a secondary and then the primary came back up. In this case since there is only one port the impact of switching ports is more noticeable and thus it may be desirable to not switch back to the original primary just because it is up. Instead traffic should only switch back if the currently active secondary fails.

To support that, the command `set priority-override` has been added for redundant interfaces. If `priority-override` is enabled, then when a port with a higher priority comes up then traffic switches to it. With `priority-override` disabled, traffic will only switch to a higher priority port if the current port fails.

Syntax

```
config system interface
   edit <name>
      set type redundant
      set priority-override {enable | disable}
   end
end
```

Link Layer Discovery Protocol

Link Layer Discovery Protocol (LLDP) is supported in FortiOS 5.2. LLDP allows a device to advertise its existence and capabilities to other devices.

The primary use for LLDP is to improve a FortiGate unit's device detection output when another FortiGate unit is detected. LLDP information is used to populate the device record on the FortiGate unit performing device detection. Any LLDP information transmitted by a peer is ignored unless FortiGate device detection is enabled on an interface. If device detection is enabled, then the subset of LLDP information sent by the peer that is relevant to device detection is shown in the `diagnose user device list` output.

The transmitted LLDP attributes on a given port are:

- Chassis ID
- Port ID
- TTL
- System Name
- System Description
- System Capabilities
- Aggregation
- Host Name

LLDP transmission is enabled by default on all ports that support a MAC address. It can be disabled globally, or disabled on some interfaces or VDOMs, while being enabled on others.

Syntax

To disable LLDP globally or on a specific VDOM, use the following command:

```
config system global
   set lldp-transmission disable
end
```

To enable LLDP at the individual interface level, first disable LLDP globally, then use the following command:

```
config system interface
   edit <name>
      set lldp-transmission enable
   end
end
```

CPU and Memory Usage per VDOM

In FortiOS 5.2, the following information sources are available concerning both CPU and memory usage per VDOM:

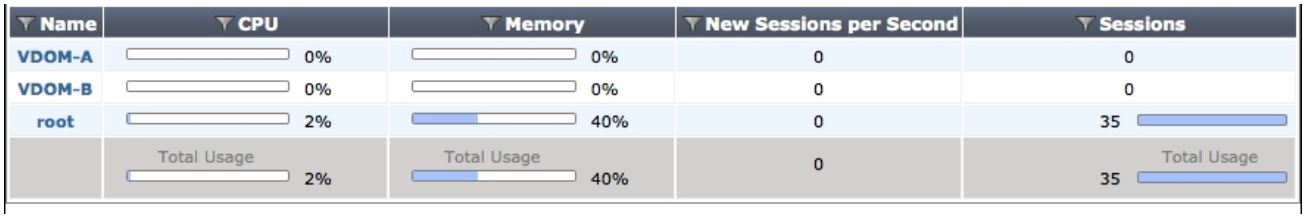
Default columns for CPU and Memory have been added to the VDOM list.

Optional columns for Sessions and New Sessions per Second have been added to the VDOM list.

A summary line has been added to at the bottom of the VDOM list to show global CPU, memory, sessions, and sessions per second usage.

The CLI command `diagnose sys vd stats` has been added to display VDOM statistics.

VDOM list



Custom Languages for Guest Management and SSL VPN Portals

Custom language files can now be used for guest management admin accounts, as well as guest portals, SSL VPN portals, and SSL VPN user settings.

To use this feature, it must be enabled in the CLI. Language files can now be managed, imported, and downloaded by going to **System > Config > Advanced**. Further configuration can be done in the CLI.

Syntax

1. Enabling the feature:

```
config system global
   set gui-custom-language enable
end
```

2. Downloading a custom language file from a TFTP server:

```
execute system custom-language import <lang_name> <file_name> <tftp_server_ip>
```

3. Managing custom languages:

```
config system custom-language
   edit <lang_name>
      set filename <file_name>
   end
end
```

4. Setting the custom language for an admin account with `guest-auth` enabled:

```
config system admin
   edit <name>
      set guest-auth enable
      set guest-lang <lang_name>
   end
end
```

5. Setting the custom language for an SSL-VPN portal with `web-mode` enabled:

```
config vpn ssl interface
   edit <name>
      set web-mode enable
      set custom-lang <lang_name>
   end
end
```

6. Setting the custom language for an SSL-VPN user:

```
config vpn ssl web user-bookmark
   edit <name>
      set custom-lang <lang_name>
   end
end
```

Packet Capture Options for Admin Profiles

Packet capture can now be configured in an admin profile and set to **None**, **Read Only**, or **Read-Write**. The packet capture option can be found by going to **System > Admin > Admin Profiles** and expanding **Firewall Configuration**.

This feature can also be configured in the CLI.

Syntax

```
config system accprofile
   edit <name>
      set fwgrp custom
         config fwgrp-permission
            set packet-capture {read-only | read-write | none}
         end
      end
end
```

FortiCloud Modem List

The supported modem list that can be downloaded from FortiCloud will now include a list of supported modems by FortiOS and the new FortiExtender unit. To support this, the file format of the list changed from plain text to tar ball that contains two files: `modem_list.conf` for the FortiOS list and `modem_list_fex.conf` for the FortiExtender list.

SPAN Support for Hard-Switch Interfaces

The Switch Port Analyzer (SPAN) feature is now available for hardware switch interfaces on FortiGate models with built-in hardware switches (for example, the FortiGate-100D, 140D, and 200D etc.). The SPAN feature (also called port mirroring) allows you to send a copy of the packets received or sent by one interface to another. So, for example, you could send all traffic received by the WAN interface to another interface and connect a sniffer to that other interface to monitor the traffic on the WAN interface.

To enable SPAN on a hardware switch, go to **System > Network > Interfaces** and edit a hardware switch interface. By default the system may have a hardware switch interface called **lan**. You can also create a new hardware switch interface.

Select the **SPAN** checkbox. Select a source port from which traffic will be mirrored. Select the destination port to which the mirrored traffic is sent. Select to mirror traffic received, traffic sent, or both.

Configuring SPAN

You can also enable SPAN in the CLI:

Syntax

```
config system virtual-switch
   edit <port>
      set span enable
      set span-source-port <port>
      set span-dest-port <port>
      set span-direction {both | Tx | Rx}
   end
end
```

Setting the Service and AC-name in PPOE PADI/PADO Negotiations

The Service and AC name in the PPPoE PADI/PADO negotiation is now configurable. This allows CLI-specified names to encoded, enhancing logic in the handling of various PPPoE server responses, especially in situations where there are multiple Access Concentrator servers in the Point of Presence site.

Syntax

```
edit port1
   set mode pppoe
   set service-name <name>
   set ac-name <name>
end
```

Disabling FortiExplorer, the USB MGMT Port, and the Serial Console

New CLI commands have been added allowing you to disable access for FortiExplorer on Windows and OS X and the USB MGMT port, or for the serial console, FortiExplorer iOS, the USB MGMT port, and 3G/4G MODEM access.

Syntax

1. Disable FortiExplorer on Windows and OS X and the USB MGMT port:

```
config system console
   set fortiexplorer disable
end
```

2. Disable serial console, FortiExplorer iOS, and 3G/4G MODEM access:

```
config system console
```

```
        set login disable
    end
```

Port Kernel Profiling

Port kernel profiling is now supported in FortiOS 5.2. To use this feature, enter the command `diagnose sys profile` into the CLI. If you press enter, the following options are available:

1. set cpu mask
2. run start command
3. run stop command to read the profiling data and analyze
4. run show command to show the result
5. set cpu mask 00 to stop profiling

The following attributes are also available:

- `cpumask` - profile which CPUs.
- `module` - show kernel module (This is only available when the kernel is module mode).
- `show` - show kernel profiling result.
- `start` - start kernel profiling data.
- `stop` - copy kernel profiling data.
- `sysmap` - show kernel sysmap.

Using a Second Destination IP (VRDST)

VRRP can now be configured with second destination IP (VRDST) for monitoring. When two IPs are used, VRRP failure will only be reported if both monitored IPs are down.

A second VRDST can be configured using the CLI.

Syntax

```
config system interface
   edit <interface>
      config vrrp
         edit <id>
            set vrdst <ip1> <ip2>
         end
      end
end
```

Session Rate Stats per VDOM

The command `diagnose sys vd list` now displays the session setup rate. This feature is supported for both IPv4 and IPv6.

Disable Honoring the Don't-Fragment Flag

Honoring the Don't-Fragment flag can now be disabled through the CLI. This allows the FortiGate unit to fragment the packet as required, even when the Don't-Fragment flag is set.

Syntax

```
config system global
   set honor-df disable
end
```

Disable Login Time Recording

Login time recording, which is enabled by default, can now be disabled using the CLI.

Syntax

```
config system global
   set login-timestamp disable
end
```

Per-IP-Bandwidth-Usage Feature Removed

The Per-IP-Bandwidth feature has been removed in FortiOS 5.2. This includes both the **Per-P-Bandwidth** widget in the web-based manager and all related CLI commands.

Modem Support

The Novatel MC679 and Sierra 313U modems are supported in FortiOS 5.2 for use with a FortiGate unit.

An MIB entry, `fgUsbModemSignalStrength`, has also been added to display modem signal strength.

Usability Enhancements

Many usability enhancements have been made to the web-based manager in FortiOS 5.2, in order to make the configuration process more efficient. New usability enhancements include:

- FortiView Dashboards
- FortiExplorer Setup Wizard Improvements
- Interfaces List Improvements
- Dragging Objects Between Policies in the Policy List
- Cloning Table Objects
- DHCP-related Improvements in the Web-based Manager
- System Resources Widget
- License Information Widget
- USB Modem Widget
- New Feature Settings Preset
- Improved Banned User List Page
- Replacement Message Improvements
- Sorting and Filtering Support for the Virtual IP list
- Web-based Manager Options for the FortiGate-30D

FortiView Dashboards

In order for information to appear in the **FortiView** dashboards, disk logging must be selected for the FortiGate unit. To select disk logging, go to **Log & Report > Log Config > Log Settings**.

Disk logging is disabled by default for some FortiGate units. To enable disk logging, enter the following command in the CLI:

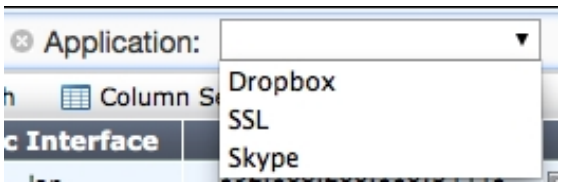
```
config log disk setting
     set status enable
end
```

Please note that flash-based logging has been disabled in FortiOS 5.2 for certain models. To view a complete list of affected models, please refer to the Release Notes.

The **FortiView** dashboards integrate real time and historical dashboards into a single view. These dashboards can be found by going to **Status > FortiView**. Each dashboard will initially display the top 100 sessions but when the results are filtered, other sessions may be displayed.

Each dashboards can be filtered by a variety of attributes. Attributes can be selected by using the dropdown menu located at the top of each widgets that displays only the options that have results; for example, if the only applications used in the are Dropbox, SSL, and Skype, the only options in the dropdown menu for the Application filter will be Dropbox, SSL, and Skype.

Filtering for Applications



Results can also be filtered using the various columns, although not all columns support this.

The dashboards also include different time options, allowing you to see current traffic in real-time, or historical traffic that occurred in the last 5 minutes, 1 hour, or 24 hours.

Historical traffic is only supported on FortiGate models that have local storage. The 24 hours option is also unavailable for desktop models (FortiGate-90 series and below).

Sources

The **Sources** dashboard shows information about the sources of traffic on your FortiGate unit, including user and device. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by source IP, source device, source interface, destination interface, and policy ID.

The Sources dashboard

Source	Device	Sessions	Bytes (Sent/Received)
10.10.80.3	Alais	122	539.94 K
10.10.80.4	Nicola	4	163.12 K
10.10.80.2	Wii	1	386

Applications

The **Applications** dashboard shows information about the applications being used on your network, including application name, category, and risk level. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by application, source interface, destination interface, and policy ID.

In order for information to appear in the **Applications** dashboard, application control must be enabled in a policy.

The Applications dashboard

Application	Category	Risk	Sessions	Bytes (Sent/Received)
DNS	Network.Service		35	9.44 K
Skype	P2P		23	589.99 K
Hola.Unblocker	Proxy		21	440.08 K
SMTPS	Email		1	10.46 K
Dropbox	Storage.Backup		1	12.11 K

Cloud Applications

The **Cloud Applications** dashboard shows information about the cloud applications being used on your network, including application name, category, risk level, login IDs, and, if applicable, the number of videos played. If the cursor is held over the column showing the number of videos, the titles of these videos will be shown. Additional columns show information about sessions and bytes sent or received.

Two different views are available for the Cloud Applications dashboard: applications and users. Applications shows a list of the programs being used. Users shows information on the individual users of the cloud applications, including the username if the FortiGate was able to view the login event.

This dashboard can be filtered by application, source interface, destination interface, and policy ID.

In order for information to appear in the **Cloud Applications** dashboard, an application control profile that has **Deep Inspection of Cloud Applications** turned on must be enabled in a policy and SSL Inspection must use `deep-inspection` (for more information, see "SSL Inspection").

The Cloud Applications dashboard

Application	Category	Risk	Login IDs	Sessions	Files (Up/Down)	Videos Played	Bytes (Sent/Receive
Youtube	Video/Audio		1	25		8	139.77 M
Vimeo	Video/Audio		1	1		1	4.85 M
Dropbox	File.Sharing		1	1	0 / 1		15.09 M

Destinations

The **Destinations** dashboard shows information about the destination IPs of traffic on your FortiGate unit, as well as the application used. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by destination IP, user, source interface, destination interface, and policy ID.

The Destinations dashboard

Destination	Applicati...	Sessions	Bytes (Sent/Received)
pongs.blip.tv (54.243.171.49)	Unknown	2	71.42 K
gwb.lphbs.com (199.127.194.181)	Unknown	1	45.33 K
notify3.dropbox.com (108.160.167.157)	Dropbox	1	555
dsn0.d.skype.net (157.55.130.156)	Unknown	1	8.29 K
dsn15.d.skype.net (157.55.56.154)	Unknown	1	3.84 K
104.0.14.6.0.rst6.r.skype.net (157.55.133.145)	Unknown	1	5.03 K

Websites

The **Websites** dashboard lists the top allowed and top blocked web sites. You can view information by domain or by FortiGuard categories by using the options in the top right corner. Each FortiGuard category can be clicked on in order to see a description of the category and several example sites, with content loaded from FortiGuard on demand. New icons have also been added for FortiGuard category groups. Additional information is provided about domain, browsing time, threat weight, sources, and bytes sent or received.

This dashboard can be filtered by source interface, domain, destination interface, and policy ID.

In order for information to appear in the **Websites dashboard**, web filtering must be enabled in a policy, with FortiGuard Categories enabled.

The Websites dashboard

Filter Website Domains... | Domains | Categories | now | 5 minutes | 1 hour | 24 hours

Domain	Category	Browsing Time	Threat Weight	Sessions	Bytes (Sent/Received)

Threats

The **Threats** dashboard lists the top users involved in incidents, as well as information on the top threats to your network. Additional information is provided about the threat, category, threat level, threat weight, and number of incidents.

This dashboard can be filtered by source interface, threat type, threat, destination interface, and policy ID.

In order for information to appear in the **Threats** dashboard, **Threat Weight Tracking** must be used.

The Threats dashboard

Threat	Category	Threat Le...	Threat Weight	Incidents
Failed Connection Attempts	Failed Connection Attempts	Medium	30	3

All Sessions

The **All Sessions** dashboard shows information about all FortiGate traffic. To choose which columns you wish to view, select **Column Settings** and place your desired columns in the right-hand box, in the order that you wish them to appear.

This dashboard can be filtered by source IP, destination IP, application, source device, source interface, destination interface, and policy ID. If you have set a filter in a different dashboard before viewing the **All Sessions** dashboard, that filter will remain until manually cleared.

The All Sessions dashboard

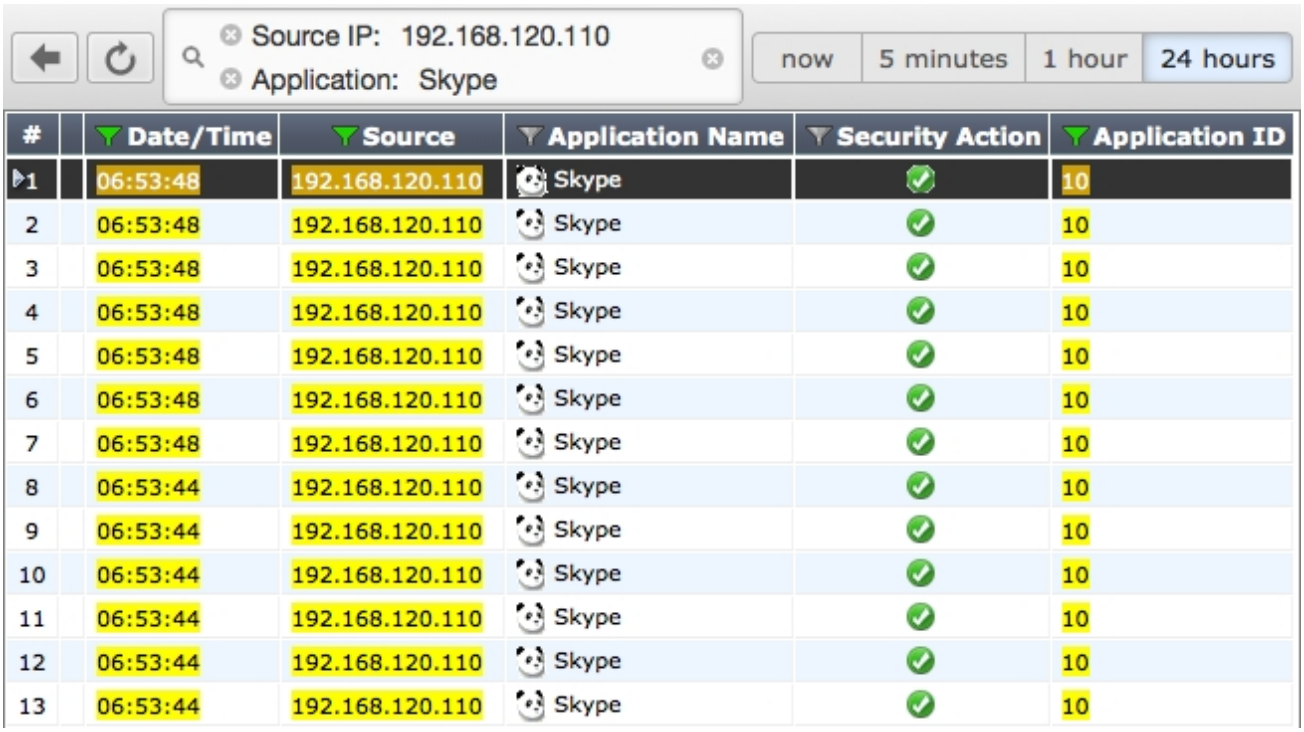
Date/Time	Source	Destination	Application Name	Security Acti...	Threat	Sent / Received
10:49:24	192.168.120.110	188.40.238.250 (analytics.eicar.org)	Unknown			4.11 KB / 11.33 KB
10:49:15	192.168.120.110	188.40.238.250 (analytics.eicar.org)	Unknown		AV EICAR_TEST_FILE	10.65 KB / 237.91 KB
10:44:33	192.168.120.110	38.127.167.7 (lastpass.com)	LastPass			2.02 KB / 8.98 KB
10:44:33	192.168.120.110	108.160.167.148 (d.dropbox.com)	Dropbox_Client.Sync			4.14 KB / 6.59 KB
10:44:26	192.168.120.110	134.170.24.141 (gateway.messenger.live.com)	Skype			10.75 KB / 33.54 KB
10:44:05	192.168.120.110	63.245.217.208 (phx-sync-13-2-8.services.mozilla.com)	SSL			8.66 KB / 4.39 KB

Drilldown Options

In all FortiView dashboards except for the **All Sessions** dashboard, you can view more information about a particular session by right-clicking or double-clicking on the session to display the **Drilldown to details...** option, which opens a summary page that includes further information about applications, sources, destinations, and sessions where applicable.

From this summary page, you can access automatically filtered logs that will show a list of applicable sessions. For example, if you have picked the IP address 192.168.120.110 from the **Sources** dashboard, you can then select **Drilldown to details...** for Skype from the **Applications** column. This will open a log that displays all sessions from 192.168.1.1 that used Skype. From this page, you can select **Drilldown to details...** for any individual session, in order to view the log entry for that session.

Viewing Skype sessions from the Source Address 192.168.120.110



#	Date/Time	Source	Application Name	Security Action	Application ID
1	06:53:48	192.168.120.110	Skype	✓	10
2	06:53:48	192.168.120.110	Skype	✓	10
3	06:53:48	192.168.120.110	Skype	✓	10
4	06:53:48	192.168.120.110	Skype	✓	10
5	06:53:48	192.168.120.110	Skype	✓	10
6	06:53:48	192.168.120.110	Skype	✓	10
7	06:53:48	192.168.120.110	Skype	✓	10
8	06:53:44	192.168.120.110	Skype	✓	10
9	06:53:44	192.168.120.110	Skype	✓	10
10	06:53:44	192.168.120.110	Skype	✓	10
11	06:53:44	192.168.120.110	Skype	✓	10
12	06:53:44	192.168.120.110	Skype	✓	10
13	06:53:44	192.168.120.110	Skype	✓	10

In the **All Sessions** dashboard, filters are also used to narrow down what results are shown. If you are viewing historical traffic in the **All Sessions** dashboard, you can also add an element to a filter by right-clicking the element and selecting **Set Filter**.

Sniffer Traffic Support

Historical traffic logging with the **FortiView** dashboards is supported for sniffer traffic.

FortiExplorer Setup Wizard Improvements

Several improvements have been made to the FortiExplorer Setup Wizard.

Removed Features

Several features have been removed from the FortiGate Setup Wizard:

- Central management configuration
- UTM: AntiSpam setup
- UTM: IPS setup
- Virtual Servers

The WAN Topology options have also been simplified so that the only option is Single Ethernet.

FortiWiFi

Several additional changes have occurred for FortiWiFi units, found in the **LAN + WiFi Settings** section of the wizard:

- The default SSID is now named `fortinetXXXX`, where XXXX is the last 4 digits of the FWF serial number.
- The default SSID is bridged with the internal network.
- The default pre-shared key is different for each FortiWiFi unit.
- A **Show Password** option has been added.

Internet Access

The following changes have been made to the **Internet Access** section of the wizard:

- Selecting **Block Viruses and Malicious Content** enables anti-virus and web filtering
- The MPAA rating system is used for **Parental Controls**

Remote VPN

In the **Remote VPN** section, an option has been added to setup dynamic DNS with FortiGuard. The option is enabled by default.

AntiVirus Inspection Mode

If the flow-based AntiVirus database is not enabled, the setup wizard will change the default profile to proxy-based.

Interfaces List Improvements

Several improvements have been made to the Interfaces List:

- Only interfaces with tunnels or VPNs expand to show more information.
- The Status column shows the number of clients using the interface. Clicking on the number in the status column will direct you to the **DHCP Monitor** or wireless **Client Monitor**, depending on which type of clients are using the interface.
- The protocols listed in the Access column have been assigned color codes. Secure services (HTTPS, SSH) are listed in grey, insecure services (TELNET, HTTP without HTTPS redirect enabled) are listed in red, and all other services are listed in blue.

The Interfaces list

Status	Name	IP/Netmask	Type	Access
	wan1	192.168.0.10 255.255.255.0	Physical	PING FMG-Access AUTO-IPSEC
	wan2	192.168.101.99 255.255.255.0	Physical	PING FMG-Access AUTO-IPSEC
	mesh.root (SSID: fortinet.mesh.root)	0.0.0.0 0.0.0.0	WiFi	
	internal	192.168.1.99 255.255.255.0	Physical	PING HTTPS SSH
	wifi (SSID: NAMAAH)	10.10.80.1 255.255.255.0	WiFi	PING HTTPS FMG-Access

Dragging Objects Between Policies in the Policy List

Objects can now be moved or copied from one policy to another in the policy list. This includes source and destination addresses, services, users, user groups, and security profiles. The default “none” object is also included.

Because of this change, a blank policy can now be created, with the configuration determined by dragging elements from other policies.

Cloning Table Objects

Table objects can now be cloned, allowing an existing object to be copied and given a new name. The object's properties can then be configured by selecting Edit.

Cloning is enabled for both Firewall Objects and Security Profiles.

DHCP-related Improvements in the Web-based Manager

A number of improvements have been made in the web-based manager, relating to DHCP:

- A DHCP Server column has been added to the interface list that shows which interfaces have been enabled as a DHCP server and the assigned IP range.
- The DHCP Client List has been improved by adding device icons and changing the Expires column to show the amount of time left on the DHCP lease.
- New addressing modes have been added to support IPv6 and PPPOE. The option for IPv6 will only appear if it has been enabled in the web-based manager, while PPPOE options only appear if IPv4 addressing is set to PPPOE as well.
- Options have been added to DHCP Monitor, allowing DCCP leases to be revoked and IP reservations to be added or edited.
- Advanced DHCP configuration can now be done through the web-based manager. To enable this feature, the following syntax must be used in the CLI:

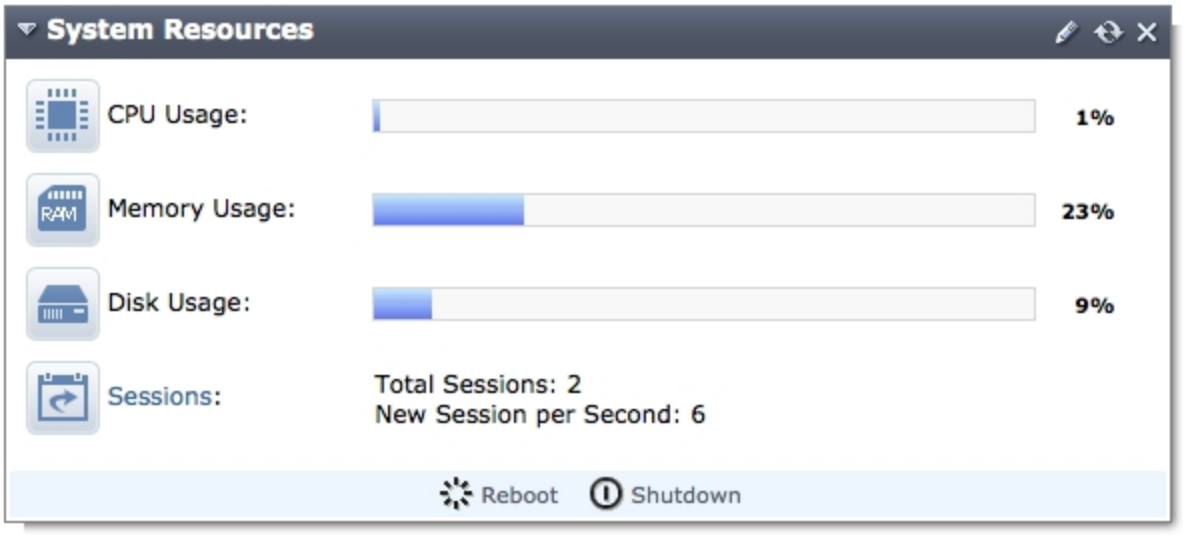
```
config system global
   set gui-dhcp-advanced enable
end
```

After this has been enabled, an **Advanced** menu can be expanded when configuring DCHP on a network interface.

System Resources Widget

The appearance of the **System Resource** widget has been changed to better illustrate the large number of CPU cores. The IPMC sensors information, about temperature, fan, and power supply unit, has also been added to the widget for some FortiGate models.

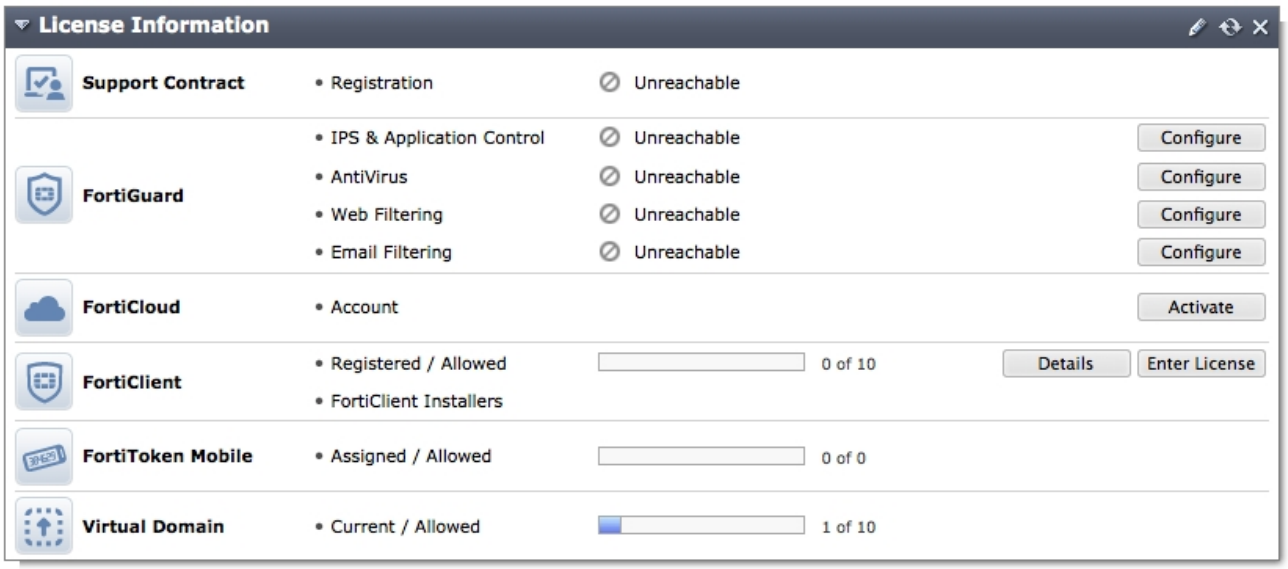
System Resources widget (on a FortiGate-100D)



License Information Widget

The appearance of the **License Information** widget has changed to clearly show the current licenses of your FortiGate. A new option has also been added to extend a license, which allows you to add a new license as soon as you buy it, rather than having to wait for the current license to expire.

License Information widget



USB Modem Widget

The following changes have occurred to the **USB Modem** widget:

- The LOC number has been removed.
- SIM State and SIM card ID fields have been added.
- MEID will be displayed if a CDMA modem is used.
- IMEI will be displayed if a GSM modem is used.

New Feature Settings Preset

A new preset, **UTM**, has been added to the Feature Settings, which are set either using the **Features** widget or by going to **System > Config > Features**. This preset turns on the following features: antivirus, web filtering, application control, and end point control. This preset is the default setting for FortiGate models 200 and below.

The preset formerly known as UTM, which turns on all features, is now called **full UTM**.

Improved Banned User List Page

The banned user list has been improved by the following changes:

- Adding a search function
- Improving sorting through column filters
- Displaying information on the event that caused the user to be quarantined

Replacement Message Improvements

The process of creating replacement message using tags and images has been simplified by the following additions:

- A right-click menu to insert tags/images
- An auto-complete feature for tags (when you begins by entering %%)
- Descriptions for each tag that appear as they are typed
- Image previews when an image tag is used
- An graphics list that allows you to select from predefined images or upload a new image
- Variables for source IP (%%SOURCE_IP%%), destination IP (%%DEST_IP%%), and user name (%%USERNAME%%) can now be added.

Sorting and Filtering Support for the Virtual IP list

In FortiOS, the virtual IP list can be sorted and filtered, allowing for easier management.

Web-based Manager Options for the FortiGate-30D

The FortiGate-30D by default views a different version of the web-based manager than other units, known as `gui-lite`. This mode can be disabled in the CLI, in order to view the standard web-based manager.

Syntax

```
config system global
   set gui-lite disable
end
```

Firewall

New firewall features include:

- Menu Simplification
- Unified Policy Management
- Importing LDAP Users for a Security Policy
- Dynamic VIP According to DNS Translation
- GTP Rate Limiting
- Object UUID Support
- Configuring the Class of Service Bit
- Hairpinning for NAT64 and NAT46
- Maximum Number of Available Virtual IPs Increased

Menu Simplification

Security policies and firewall objects are now found in the same menu, called **Policy & Objects**.

Policies

The menu option for policies, found at **Policy & Objects > Policy,** has been expanded to include the following policy types:

- IPv4
- IPv6
- NAT64
- NAT46
- DoS
- IPv6 DoS
- Multicast
- Local In
- Central NAT Table
- Proxy Options
- SSL Inspection (SSL/SSH Inspection on some FortiGate models)

Objects

The following firewall objects have been grouped together under a single menu, found at **Policy & Objects > Objects**:

- Addresses
- Services
- Schedules
- Traffic Shapers

- Virtual IPs
- IP Pools

Other changes have been made for specific features.

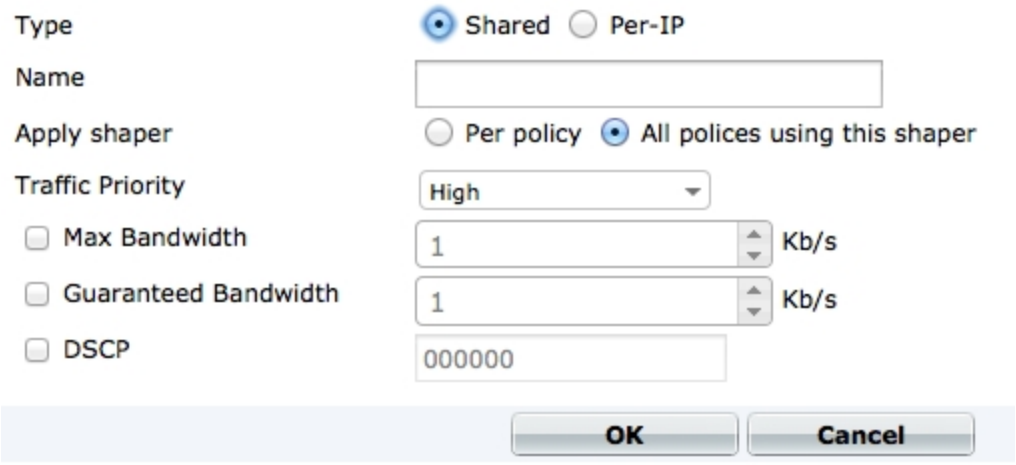
Groups

Object groups can now be made by expanding the arrow beside **Create New** and selecting **Group.**

Traffic Shapers

Shared and Per-IP shapers have been combined into a single page, with a **Type** field added to the creation page.

Traffic shapers creation screen



An additional column, **Type,** has also been added to the traffic shapers table.

Unified Policy Management

The different creation pages in the web-based manager for policy types and subtypes (user-identity, device identity, and VPN) have been merged into a single main policy creation page. New fields have been added for **Source User(s)** and **Source Device Type** that remove the need for multiple authentication rules in a single policy. This allows for greater control and customization of policies, as a combination of these source types can be used in a single policy rather than having to pick one type.

The policy creation page

If both **Source User(s)** and **Source Device Type** are set, then traffic must match both fields in order to be accepted by the policy. Both these fields are optional; only **Source Address** must be set.

For policies that require user or device authentication, there is an implicit fall-through to allow traffic to be checked against other policies if it does not match the authentication requirements. This option cannot be disabled and the CLI command `set fall-through-unauthenticated` has been removed.

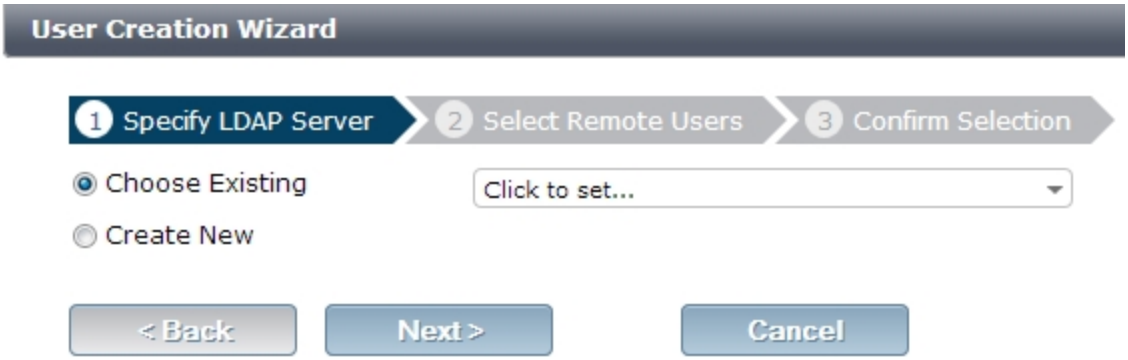
For more information about security policies in FortiOS 5.2, please see the FortiGate Cookbook recipe Creating security policies.

To create a policy for SSL VPNs, an SSL VPN interface is created and used as the source interface. For more information about this interface creation, see SSL VPN Configuration on page 132.

Importing LDAP Users for a Security Policy

The LDAP user importing wizard can now be launched during the creation of a new security policy, by selecting **Import LDAP users** in the dropdown menu when you are adding users to the policy.

The LDAP user importing wizard



Dynamic VIP According to DNS Translation

Dynamic virtual IPs according to DNS translation can now be configured.

When a dynamic virtual IP is used in a policy, the dynamic DNS translation table is installed along with the dynamic NAT translation table into the kernel. All matched DNS responses will be translated and recorded regardless if they hit the policy. When a client request hits the policy, dynamic NAT translation will occur if it matches a record, otherwise the traffic will be blocked.

Syntax

```
config firewall vip
   edit 1
      set type dns-translation
      set extip 192.168.0.1-192.168.0.100
      set extintf dmz
      set dns-mapping-ttl 604800
      set mappedip 3.3.3.0/24 4.0.0.0/24
   end
end
```

GTP Rate Limiting

New methods of GPRS Tunneling Protocol (GTP) rate limiting are available in FortiOS 5.2.

Per-Stream Rate Limiting

FortiOS 5.2 supports per-stream rate limiting of GTP and the ability to apply rate limiting separately for GTPv0 and GTPv1, as well as for GTPv2.

This feature required the addition of the following CLI commands: `message-rate-limit-v0`, `message-rate-limit-v1`, and `message-rate-limit-v2`. The commands `message-rate-limit-v0` and `message-rate-limit-v1` are only visible when `rate-limit-mode` is set to `per-stream`, while message-rate-limit is visible when rate-limit-mode is set to `per-profile`. The command `message-rate-limit-v2` is always visible, since GTPv2 message numbering and naming are different from GTPv0/v1.

The following features have also been added:

- Warning limit support.
- Per-version message rate limiting.
- A log for rate limiting warning called `rate-limited-warning`.

In addition, FortiOS Carrier now indicates the GTP version in rate limiting log messages and writes a rate limiting warning log message when a packet exceeds the rate limiting threshold.

Syntax

```
config firewall gtp
   edit <name>
      set rate-limit-mode {per-profile | per-stream}
      set warning-threshold {0-99}
      config {message-rate-limit-v0 | message-rate-limit-v1 | message-rate-limit-v2}
         set create-pdp-request <rate-limit>
         set delete-pdp-request <rate-limit>
```

```
        set echo-request <rate-limit>
    end
end
```

Per-APN Rate Limiting Profiles

In FortiOS 5.2, GTP rate limiting profiles can be based per-APN, as well as per-IP. To use this feature, the rate limit for each specific APN needs to be configured in the CLI, as there is no default rate limit.

Syntax

```
config firewall gtp profile
   set rate-limit-mode per-apn
   config per-apn-shaper
      edit <ID>
         set apn <string>
         set version <version>
         set rate-limit <rate-limit>
      end
end
```

Object UUID Support

UUID is only supported on large-partition platforms (>=128M).

A Universally Unique Identified (UUID) attribute has been added to some firewall objects, including virtual IPs and virtual IP groups for IPv4, IPv6, NAT46, and NAT64, so that the logs can record these UUID to be used by a FortiManager or FortiAnalyzer unit.

The UUID of an object can either be generated automatically or assigned through the CLI. To view the UUID for these objects in a FortiGate unit's logs, `log-uuid` must be set to `extended mode`, rather than `policy-only`, which only shows the policy UUID in a traffic log.

Syntax

```
config sys global
   set log-uuid {disable | policy-only | extended}
end

config firewall {policy | policy6 | policy46 | policy64 | address| addres6 | addgrp |
    addgrp6}
   edit <1>
      set uuid <8289ef80-f879-51e2-20dd-fa62c5c51f44>
   end
end
```

Configuring the Class of Service Bit

FortiGate units can now configure the value of the Class of Service (CoS) bit, also called Priority Code Point (PCP).

The value of CoS in forward direction (fwd) and reverse direction (rev) is set in the policy/policy6 table using the CLI. The value can be set either as 255, to allow passthrough, or given a priority between 0 and 7.

Syntax

```
config firewall {policy | policy6}
   set vlan-cos-fwd <int>
   set vlan-cos-rev <int>
end
```

Hairpinning for NAT64 and NAT46

In FortiOS 5.2, NAT64 and NAT46 support hairpinning between hosts that are located in the same network behind a single external IP address. Hairpinning allows endpoints on the internal network to communicate using external IP addresses and ports.

In order to allow hairpinning, `set permit-any-host` must be enabled in the NAT64 or NAT46 firewall policy.

Maximum Number of Available Virtual IPs Increased

The maximum limit of available virtual IPs has been increased on 1U FortiGate models (FortiGate-100 to 800 series) to 16,000 and on 2U FortiGate models (FortiGate-1000 to 3810 series) to 32,000.

Security Profiles

New security profiles features include:

- Menu and Options Simplification
- SSL Inspection
- Web Filtering
- Application Control
- Flow-based Antivirus
- Intrusion Protection System (IPS)
- Vulnerability Scanning Visibility
- Removed IM Proxy Options from CLI
- Client Reputation

Menu and Options Simplification

The menus and options for security profiles have changed in several ways. The basic profile/sensor/settings options have been left in the menu for each feature, while extra tables are now located in the **Advanced** menu. Other changes have been made for specific features.

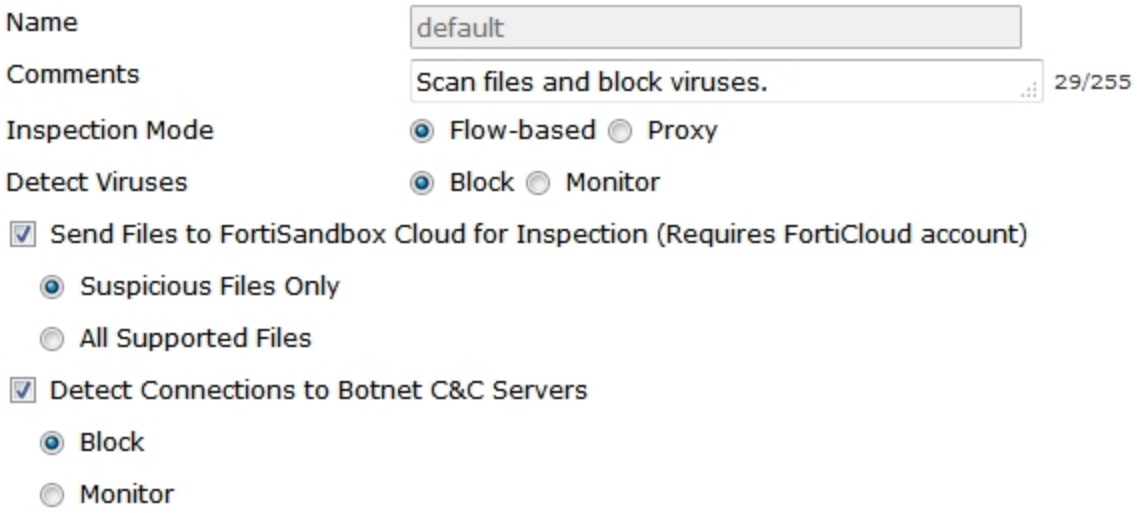
AntiVirus

Several changes have been made for the configuration options in AntiVirus profiles, as visible options change depending on whether **Inspection Mode** is set to **Flow-based** or **Proxy**.

Flow-based Profile Options

If flow-based inspection is used for AntiVirus, you can configure whether to send files to **FortiSandbox Cloud** for inspection as well as the actions to be taken for detected viruses, and for connections to **Botnet C&C** servers. You can send suspicous files or all supported files to FortiSandbox cloud. Detect Viruses and connections to Botnet C&C Servers can be set to either Block or Monitor.

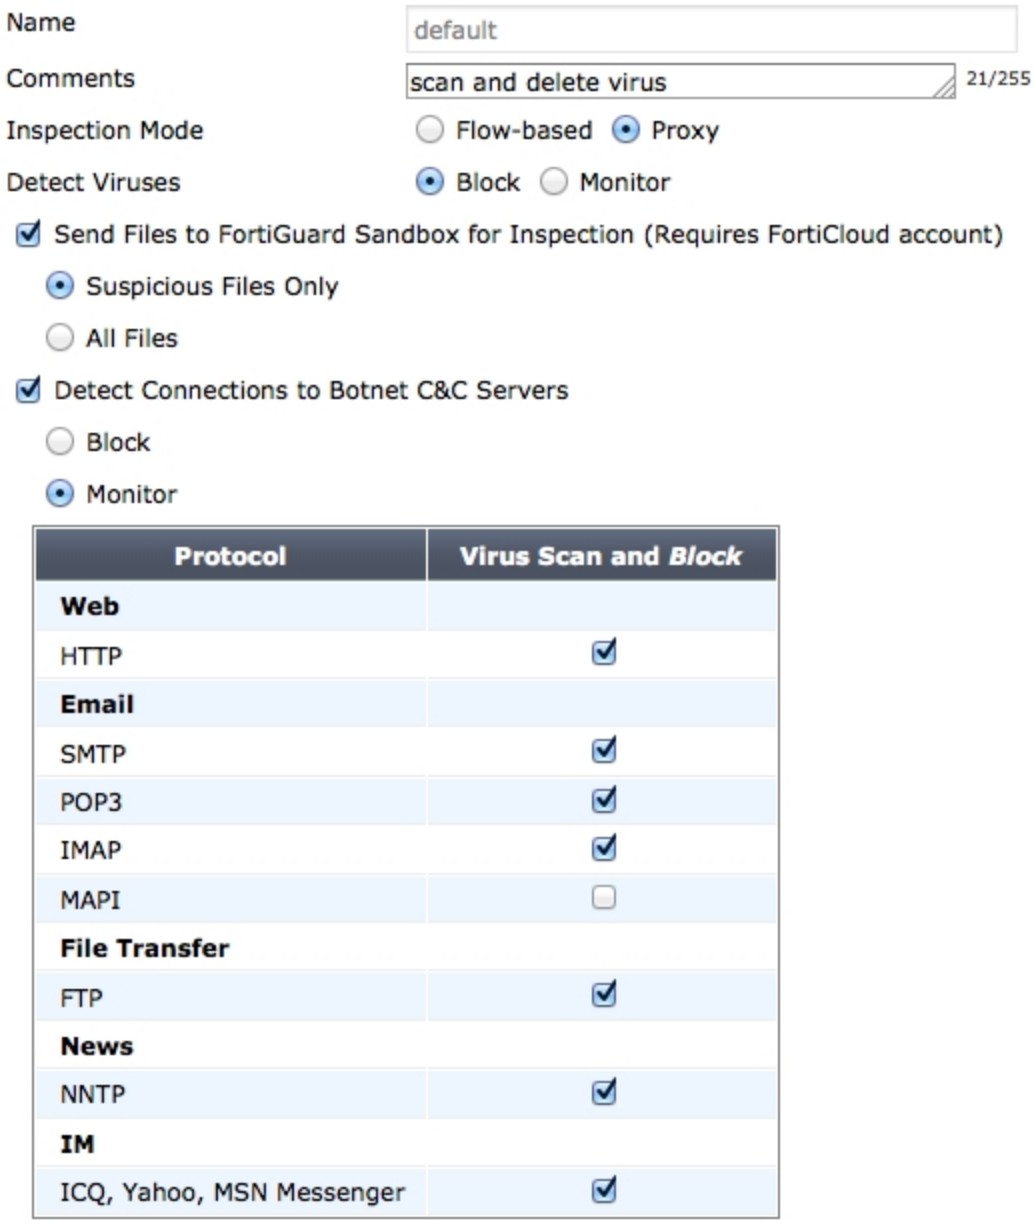
Flow-based options for AntiVirus



Proxy Options

If proxy inspection is used for AntiVirus, the addition **Block** or **Monitor** options are available for both detected viruses and Botnet C&C servers. The previous options for using FortiSandbox and protocol selection are also available.

Proxy options for AntiVirus



Protocol	Virus Scan and *Block*
Web	
HTTP	☑
Email	
SMTP	☑
POP3	☑
IMAP	☑
MAPI	☐
File Transfer	
FTP	☑
News	
NNTP	☑

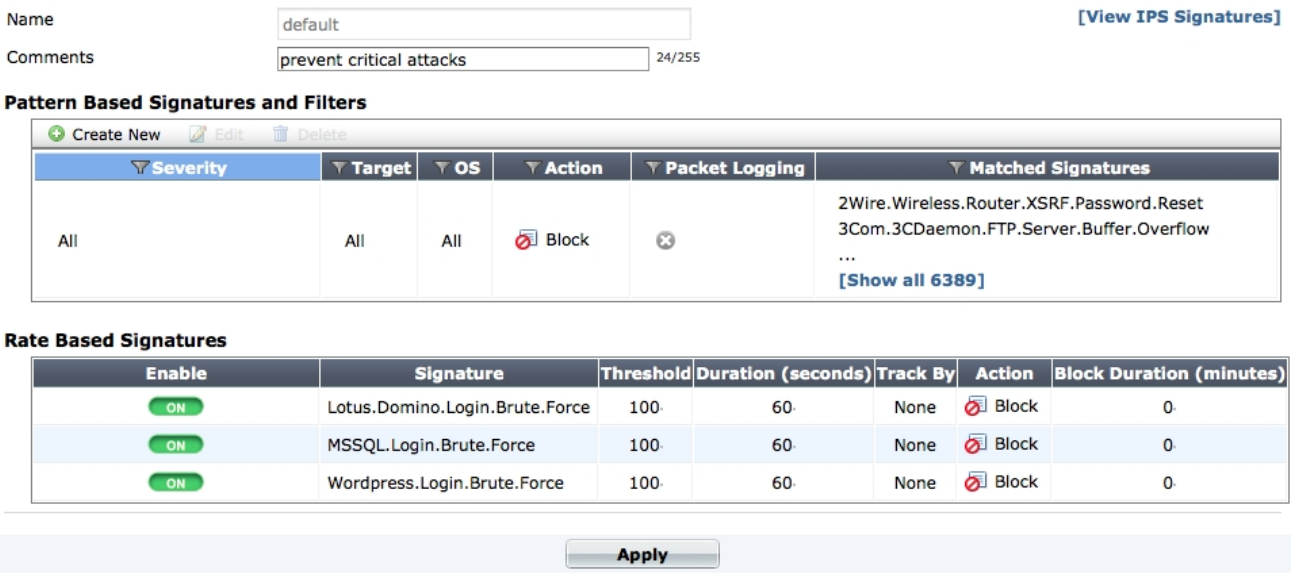
Intrusion Protection

The IPS sensor page now contains options for **Pattern Based Signatures and Filters** and **Rate Based Signatures**. The full list of IPS Signatures can be accessed from the sensor page by selecting **View IPS Signatures**.

The IPS sensor page

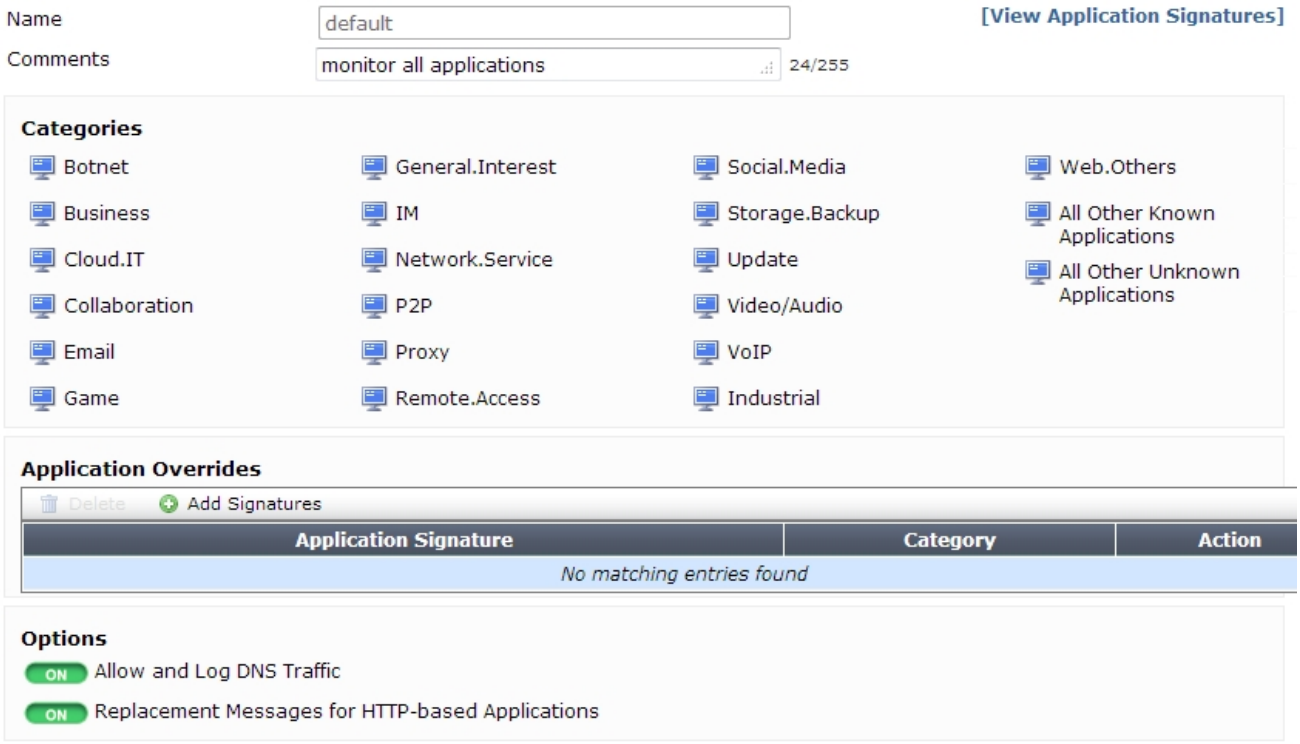


Application Control

The following changes have been made to improve usability in the web-based manager:

- A new category list has been made that appears on the sensor page, found by going to **Security Profiles > Application Control**. When you click on a category, a drop down menu appears, allowing the action for that category to be changed. You can also select to view all the application control signatures for that category.
- Application signatures can be viewed by selecting **View Application Signatures**.
- **Application Overrides** allow you to change the action taken for specific signatures/applications.
- The application filter sorting criteria popularity, technology, and risk have been removed.

The application control sensor page



Advanced Options

A new advanced menu has been added that contains the following features:

- Web rating overrides
- Web profile overrides
- DLP fingerprinting

Web Rating Overrides can also now be used to edit or delete custom website categories.

SSL Inspection

There have been several changes to how SSL Inspection is handled on a FortiGate unit.

Automatic Inspection When Security Profiles are Used

If any security profile is used in a security policy, SSL inspection will automatically be enabled, at which point an SSL mode must be selected (see below for more details).

HTTPS Scanning Without Deep Inspection

The following changes have been made in order to allow HTTPS traffic to be scanned without enabling deep inspection:

- There are now two modes for SSL inspection: certificate inspection (`certificate-inspection` in the CLI), which only inspects the SSL handshake, and `deep inspection (deep-inspection` in the CLI), which enables full deep inspection of SSL traffic (this was previously the default mode for SSL inspection).
- The CLI command `https-url-scan` has been removed.
- `deep-inspection-options` has been renamed `ssl-ssh-profile`.
- The SSL `inspect-all` option and the `https status` option now have three states: `disable`, `certificate-inspection`, and `deep-inspection`. The status option for the other protocols now use `deep-inspection` instead of `enabled`.

When a new policy or profile group is created, the SSL inspection profile `certificate-inspection` is automatically added.

SSL/Deep Inspection Exemptions

The options for configuring exemptions to SSL/Deep Inspection is now configured as part of the deep inspection options, rather than FortiGuard web filtering. Exemptions can be added to SSL inspection by going to **Policy & Objects > Policy > SSL Inspection** or through the CLI.

Certain applications, such as iTunes and Dropbox, require a specific certificate to be used, rather than using the use the system's certifciate store. Because of this, the default deep inspection profile, `deep-inspection`, has exemptions configured for these applications by default in FortiOS 5.2.

Syntax

```
config firewall ssl-ssh-profile
   edit <name>
      config ssl-exempt
         edit <id>
            set type {fortiguard-category | address | address6}
            set category <id>
            set address <string>
         end
   end
```

Generating Unique CA and Server Certificates

A FortiGate unit will now generate default SSL inspection CA and server certificates that are unique to that unit the first time the certificates are required. Previously, FortiGate units all have the same default CA and server certificates.

There are some exceptions: for example, in a HA cluster all FortiGate units need the same CA and server certificates. The certificates can also be changed as required for load balancing and other configurations.

Existing customers will not be affected by this change, as FortiOS 5.2 will not change the current defaults on upgrade.

You can use the CLI commands below to generate new certificates that will be unique to your FortiGate unit.

The following command re-generates the default SSL inspection CA certificate:

```
execute vpn certificate local generate default-ssl-ca
```

The following command re-generates the default SSL inspection server certificate:

```
execute vpn certificate local generate default-ssl-serv-key
```

Server Certificates

In FortiOS 5.2, two methods are available to support server certificates and allow inbound traffic to be inspected: **Multiple Clients Connecting to Multiple Servers** (`re-sign` in the CLI) or **Protecting SSL Server** (`replace` in the CLI).

The default setting for SSL Inspection is **Multiple Clients Connecting to Multiple Servers.** This setting can be changed by going to **Policy & Objects > Policy > SSL Inspection** or through the CLI.

Syntax

- Uploading a new server certificate:

```
config firewall ssl-ssh-profile
   edit <name>
      set server-cert-mode replace
      set server-cert <certificate>
   end
end
```

- Re-signing the server certificate:

```
config firewall ssl-ssh-profile
   edit <name>
      set server-cert-mode re-sign
      set caname <name>
      set certname <name>
   end
end
```

Web Filtering

There have been several changes made to web filtering in FortiOS 5.2.

HTTPS for Warnings and Authentication

HTTPS protocol can now be used when sending web filtering warnings or requiring a user to authenticate, including authentication for web filter overrides.

Syntax

```
config webfilter fortiguard
   set ovrd-auth-https enable
   set warn-auth-https enable
end
```

Modifying HTTP Request Headers

In FortiOS 5.2, you can add, modify, and remove header fields in HTTP request when scanning web traffic in proxy-mode. If a header field exists when your FortiGate receives the request, its content will be modified based on the configurations in the URL filter.

Syntax

```
config web-proxy profile
```

```
edit <name>
   config headers
      edit <ID>
         set name <name>
         set content <string>
      end
end
```

Restrict Google Access to Corporate Accounts

A new option has to web filtering to restrict Google access to specific domains. This allows you to block access to some Google accounts and services while allowing access to corporate Google accounts.

To use this option, go to **Security Profiles > Web Filter** and select **Restrict Google Account Usage to Specific Domains** under **Proxy Options**. You can then add the appropriate Google domains that will be allowed.

After the web filter profile has been created, this feature is applied differently in the case of transparent proxy vs. explicit proxy. For transparent proxy, the web filter profile is added to a security policy. For explicit proxy, the web filter profile must be added to an explicit proxy profile.

This feature can also be configured using the CLI, where use of the Modifying HTTP Request Headers feature (see above) is required. In the following example, access to Personal Gmail accounts is blocked while access to Google Business Mail is allowed.

Syntax

1. The web-proxy profile is configured to with a modified header:

```
config web-proxy profile
   edit "restrict-google-accounts-1"
      config headers
         edit 1
            set name "X-GoogApps-Allowed-Domains"
            set content "example.com"
         end
   end
```

2. A URL filter is configured to use the web-proxy profile:

```
config webfilter urlfilter
   edit 1
      set name "GMAIL_TEST"
      config entries
         edit 1
            set url "*.google.com"
            set type wildcard
            set action allow
            set web-proxy-profile "restrict-google-accounts-1"
         end
   end
```

3. A webfilter profile is configured that uses the URL filter:

```
config webfilter profile
   edit "GMAIL_TEST"
      ......
      config web
         set urlfilter-table 1
```

```
      end
      config ftgd-wf
         ......
      end
end
```

4. **Transparent proxy -** the webfilter profile is applied to a security policy:

```
config firewall policy
   edit 1
      set srcintf "LAN"
      set dstintf "WAN"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ALL"
      set utm-status enable
      set webfilter-profile "GMAIL_TEST"
      set profile-protocol-options "default"
      set ssl-ssh-profile "deep-inspection"
      set nat enable
   end
end
```

5. **Explicit proxy -** the web-proxy policy and the web filer profile are applied to an explicit proxy policy:

```
config firewall explicit-proxy-policy
   edit 1
      set proxy web
      set dstintf "WAN"
      set srcaddr "all"
      set dstaddr "all"
      set service "webproxy"
      set action accept
      set schedule "always"
      set webproxy-profile "restrict-google-accounts-1"
      set utm-status enable
      set webfilter-profile "GMAIL_TEST"
      set profile-protocol-options "default"
      set ssl-ssh-profile "deep-inspection"
   end
end
```

Referer Added to URL Filtering

You can now add a referer to URL filters. If a referer is specified, the host name in the referer field of the HTTP require will be compared for any entry that contains the matching URL. If the referer matches, then the specified action will be performed by proxy.

The referer can also be set in the web-based manager, but only if advanced web filter features has been enabled using the following command:

```
config system global
   set gui-webfilter-advanced enable
end
```

After this command is used, a new column will be created in **Security Profiles > Web Filter > Static URL Filter** to set the referer.

The command `set referrer-host` has been added to the CLI. The CLI has also changed so that URL filters are now identified by their IDs, and the URL values can be set under each entry.

Syntax

```
config webfilter urlfilter
   edit <ID>
      config entries
         edit 1
            set url <url>
            set referrer-host <url>
            set type {simple | regex | wildcard}
            set action {block | allow | monitor | exempt}
            set status {enable | disable}
         end
   end
```

FortiGuard Rating Checks for Images, JavaScript, CSS, and CRL

Web filter profiles that use FortiGuard rating checks can now be configured to rate images, JavaScript, CSS, and CRL.

Syntax

```
config webfilter profile
   edit <name>
      config ftgd-wf
         set rate-javascript-urls enable
         set rate-css-urls enable
         set rate-crl-urls enable
         set rate-image-urls enable
      end
end
```

Additional Replacement Message Variables

Along with the variables for source IP (%%SOURCE_IP%%), destination IP (%%DEST_IP%%), and user name (%%USERNAME%%) that have been added for all replacement messages, the following variables can now be added to replacement messages for web filtering:

- Group name (%%GROUPNAME%%)
- Policy UUID (%%POLICY_UUID%%)
- FortiGate Hostname (%%FGT_HOSTNAME%%)

New Daemon for Overrides and Warnings

The new daemon `ovrd` is used in FortiOS 5.2 to handle user-level webfilter overrides and warnings.

Application Control

There have been several changes made to application control.

Deep Inspection for Cloud Applications

Deep inspection allows the following information to be examined and logged for cloud applications:

Information about user logins and file transfers for cloud applications.

Video names will be shown in the **Application Details** column for video streaming applications such as Youtube and Vimeo.

The following new fields have been added to both the application control log and to traffic logs: cloud user, cloud action, file name, and file size.

To enable this feature, turn on **Deep Inspection of Cloud Applications** in an application control profile. It can also be enabled using the CLI.

Syntax

```
config application list
   edit <name>
      set deep-app-inspection enable
   end
end
```

Using the CLI, you can specify a global timeout for the deep application control database. Any database entries that exceed the timeout will be deleted. A global size threshold on the number of entries in the deep application control database can also be set.

When the total number of entries exceeds this threshold, the internal timeout value will be reduced to accelerate entry retiring. Both values are set to 0 (unlimited) by default.

Syntax

```
config ips global
   set deep-app-insp-timeout <integer>
   set deep-app-insp-db-limit <integer>
end
```

A new option, `--deep_ctrl`, has also been added to the syntax for IPS/application control signatures.

Several new CLI commands have also been added for diagnose and debugging:

- `diagnose ips dac info`
- `diagnose ips dac clear`
- `diagnose ips debug enable dac`

Traffic Shaping Settings

Traffic shaping settings can be applied to categories of applications that are part of the application control sensor.

To apply settings, select a category and set it to **Traffic Shaping.** The **Traffic Shaping Settings** options will appear, allowing you to select the settings for forward and reverse traffic shaping. These settings will be applied to all categories set to **Traffic Shaping** in your application control sensor.

5-Point-Risk Rating

A new rating system will be used for all pages related to application control, including the application list, the application filters list, traffic logs, the **FortiView Applications** dashboard, and the **FortiView All Sessions** dashboard. Risk levels are indicated in the various tables and logs by using a series of icons.

The rating system is as follows:

Icon	Risk Level	Description	Example
	Critical	Applications that are used to conceal activity to evade detection	Tor, SpyBoss
	High	Applications that can cause data leakage, or prone to vulnerabilities or downloading malware	Remote Desktop, File Sharing, P2P
	Medium	Applications that can be misused	VoiP, Instant Messaging, File Storage, WebEx, Gmail
	Elevated	Applications are used for personal communications or can lower productivity	Gaming, Facebook, Youtube
	**Low**	Business Related Applications or other harmless applications	Windows Updates

Replacement Message

A replacement message has been added that will appear when an application has been blocked.

This replacement message can be enabled in the CLI.

Syntax

```
config application list
   edit <name>
      set app-replacemsg {enable | disable}
   end
end
```

Support for SPDY Protocol

The SPDY protocol, and its required SSL/TLS component, is now recognized within application control profiles. It is counted as part of application traffic for Google and other sources that use the protocol.

Support for Non-HTTP WAN Optimization and Explicit Proxy Traffic

Application control is now supported for both non-HTTP WAN optimization traffic and explicit proxy traffic.

Flow-based Antivirus

In FortiOS 5.2, flow-based AntiVirus has been improved to have the same enhanced performance as flow-based antivirus scanning in FortiOS 5.0 while providing the same accuracy and many of the extended features of proxy-based antivirus.

Flow-based AntiVirus now allows data to accumulate until it detect the end of a file. When the end is reached, traffic is paused and data is sent asynchronously for analysis. When the results are received, the traffic is either allowed to resume or the connection is reset.

Because of this change, the default AntiVirus profile on a FortiGate uses flow-based inspection. Flow-based inspection can also utilize the extended AntiVirus database. Detecting and reporting only occurs when AntiVirus is enabled in the security policy.

Flow-based AntiVirus is also supported for sniffer policies.

Intrusion Protection System (IPS)

There have been several changes made to intrusion protection system (IPS).

Adjusting Rate Based Signatures

Setting for rate based IPS signatures can now be edited in the web-based manager as part of an IPS sensor. In each sensor, you can enable a selected list of rate based signatures and adjust threshold, duration, track by setting, action, and block duration.

Rate Based Signatures list

Rate Based Signatures

Enable	Signature	Threshold	Duration (seconds)	Track By	Action	Block Duration (minutes)
ON	Lotus.Domino.Login.Brute.Force	100	60	None	Block	0
ON	MSSQL.Login.Brute.Force	100	60	None	Block	0
ON	Wordpress.Login.Brute.Force	100	60	None	Block	0

Extensible Meta Data

Extensible meta data allow you to specify custom options in IPS signatures that are delivered to your FortiGate without interpretation, in order to make signatures easier to find and understand for the FortiGate administrator. Four types of meta data options are supported: integers, bitmaps, enumerables, and strings.

Example

In this example, a set of meta data is declared and then used to create IPS signatures.

The meta data is declared:

```
F-META2( --name points; --index 12; --type integer; )
F-META2( --name flags; --index 34; --type bitmap; --value foo:1; --value bar:2; --value
    baz:4; )
F-META2( --name dr_seuss; --index 56; --type enum; --value "One Fish":1; --value "Two
    Fish":2; --value "Red Fish":3; --value "Blue Fish":4; )
F-META2( --name secret; --index 78; --type string; )
```

The meta data is used:

```
F-SBID( --points 42; ... )
F-SBID( --flags foo; --flags baz; ... )
F-SBID( --dr_seuss "One Fish"; ... )
F-SBID( --secret "Abracadabra"; ... )
```

Extended Database

In FortiOS 5.2, the IPS extended database is enabled by default for all FortiGate models that have multiple CP8.

Support for Non-HTTP WAN Optimization and Explicit Proxy Traffic

IPS is now supported for both non-HTTP WAN optimization traffic and explicit proxy traffic.

Vulnerability Scanning Visibility

The options to configure vulnerability scanning either in the web-based manager or the CLI are also only available in NAT/Route mode.

Vulnerability scanning options in the web-based manager are now hidden by default. To enable vulnerability scanning, go to **System > Config > Features**, select **Show More**, turn on **Vulnerability Scan**, and select **Apply**.

Vulnerability scanning is also hidden by default for FortiClient profiles until being enabled in the CLI. To enable scanning, enter the following commands:

```
config endpoint-control profile
   edit <profile-name>
      config forticlient-winmac-settings
         set forticlient-vuln-scan {enable | disable}
         set forticlient-vuln-scan-schedule {daily | weekly | monthly}
         set forticlient-vuln-scan-on-registration {enable | disable}
         set forticlient-ui-options {av | wf | af | vpn | vs}
      end
end
```

Removed IM Proxy Options from the CLI

The proxy options related to instant messaging (IM) functions and attributes have been removed from the CLI in FortiOS 5.2. This includes the following commands:

- `config imp2p`
- `get imp2p`
- The DLP sensor options for AIM, ICQ, MSN, and Yahoo protocols.
- The AntiVirus profile option `config im`.
- The AntiVirus quarantine options for IM.
- The Application Control profile options for IM.
- The firewall profile protocol options for IM.

Client Reputation

The 5.0 feature client reputation has been renamed Threat Weight in FortiOS 5.2 and has been moved from Security Profiles to **Log & Report > Log Config > Threat Weight**. It can now be configured in the CLI using the command `config log threat-weight`.

IPsec VPN

New IPsec VPN features include:

- VPN Creation Wizard
- Internet Key Exchange (IKE)
- Dynamic IPsec Route Control
- Default Lifetimes and Proposal Values
- Prioritizing DH Group Configuration
- IPv6 Support for IPsec Phase 2
- IPsec VPN Support with the FortiController-5103B

VPN Creation Wizard

Several improvements have been made to the **VPN Creation Wizard.**

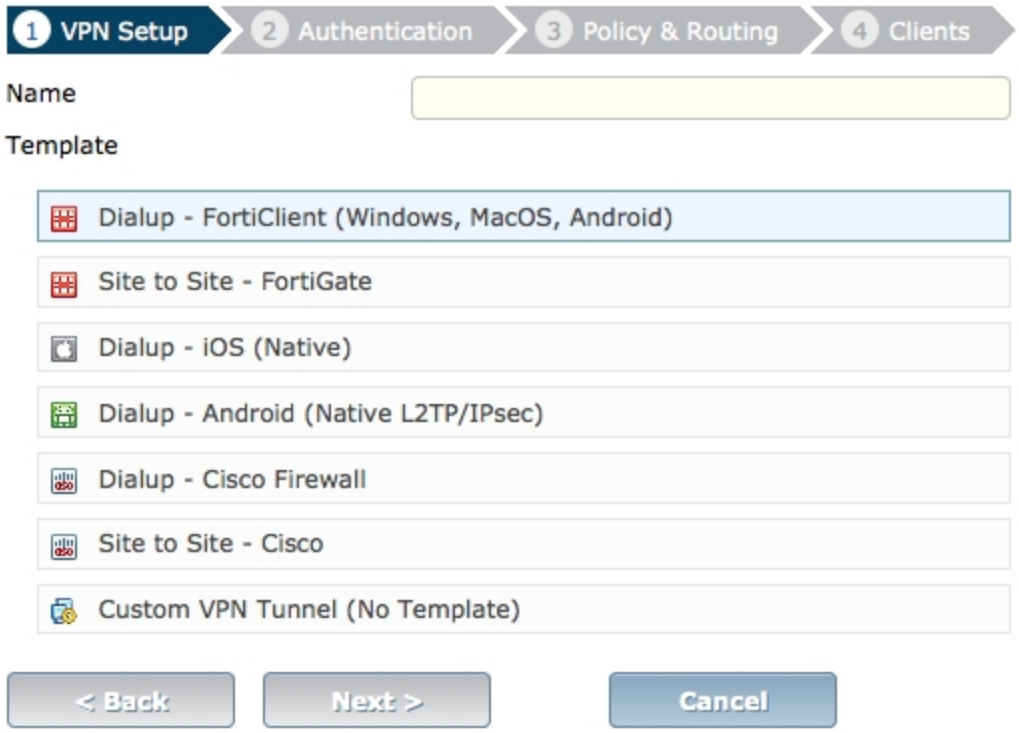
New Menu

The Wizard can now be found by going to **VPN > IPsec > Wizard.**

Expanded VPN Options

The number of VPN options available in the Wizard has increased to allows you to easily create VPN tunnels for a greater variety of scenarios.

Expanded VPN Options for the VPN Creation Wizard



For more information about using the VPN Wizard, see The FortiGate Cookbook recipe IPsec VPN for iOS devices.

Tunnel Templates

Several tunnel templates have been added to the Wizard that cover a variety of different types of IPsec VPNs. A list of these templates appears on the first page of the Wizard, which is found by going to **VPN > IPsec > Tunnels**.

To view more information about a template, highlight the template and select **View.**

Tunnel Templates list

Template	Description
Dialup - FortiClient (Windows, MacOS, Android)	On-demand tunnel for users using the FortiClient software.
Site to Site - FortiGate	Static tunnel between this FortiGate and a remote FortiGate.
Dialup - iOS (Native)	On-demand tunnel for iPhone/iPad users using the native iOS IPsec client.
Dialup - Android (Native L2TP/IPsec)	On-demand tunnel for Android users using the native L2TP/IPsec client.
Dialup - Cisco Firewall	On-demand tunnel for users using the Cisco IPsec client.
Site to Site - Cisco	Static tunnel between this FortiGate and a remote Cisco firewall.

Internet Key Exchange (IKE)

There have been several changes in FortiOS 5.2 made concerning Internet Key Exchange (IKE) protocol.

Multiple Interfaces

An IPsec policy can now contain multiple source and destination interfaces. This feature is supported for combinations of IPsec interfaces, physical interfaces, and zones (including those with a combination of physical and IPsec interfaces).

It is not supported for SSL VPN interfaces.

Mode-Configuration

When IKE Mode-Configuration is enabled, multiple server IPs can be defined in IPsec Phase 1. This mode also allows IP information to be sent the client if attribute 28681 is requested.

Mode-Configuration is configured through the CLI. An example of a complete configuration is shown below:

```
config vpn ipsec phase1-interface
   edit "vpn-p1"
      set type dynamic
      set interface "wan1"
      set xauthtype auto
      set mode aggressive
      set mode-cfg enable
      set proposal 3des-sha1 aes128-sha1
      set dpd disable
      set dhgrp 2
      set xauthexpire on-rekey
      set authusrgrp "FG-Group1"
      set ipv4-start-ip 10.10.10.10
      set ipv4-end-ip 10.10.10.20
      set ipv4-dns-server1 1.1.1.1
      set ipv4-dns-server2 2.2.2.2
      set ipv4-dns-server3 3.3.3.3
      set ipv4-wins-server1 4.4.4.4
      set ipv4-wins-server2 5.5.5.5
      set domain "fgt1c-domain"
      set banner "fgt111C-banner"
      set backup-gateway "100.100.100.1" "100.100.100.2" "host1.com" "host2"
   end
end
```

Certificates Groups

IKE certificate groups consisting of up to four RSA certificates can now be used in IKE phase 1. Since CA and local certificates are global, the IKE daemon loads them once for all VDOMs and indexes them into trees based on subject and public key hash (for CA certificates), or certificate name (for local certificates). Certificates are linked together based on the issuer, and certificate chains are built by traversing these links. This reduces the need to keep multiple copies of certificates that could exist in multiple chains.

IKE certificate groups can be configured through the CLI.

Configuring the IKE local ID

```
config vpn certificate local
   edit <name>
      set ike-localid <string>
      set ike-localid-type {asn1dn | fqdn}
   end
end
```

Adding certificates to the group

```
config vpn ipsec {phase1 | phase1-interface}
   edit <name>
      set rsa-certificate <name>
   end
end
```

Authentication Methods

Three new authentication methods have been implemented for IKE: ECDSA-256, ECDSA-384, ECDSA-521.

In order to support these three methods, the following changes have been made to the CLI:

1. `rsa-signature` has been renamed to `signature` for both policy-based and interface-based IPsec VPN.
2. `rsa-certificate` has been renamed to `certificate` for both policy-based and interface-based IPsec VPN.

Inheriting Groups from the Security Policy

IPsec VPNs can now be configured to authenticate users again the group(s) specified in a policy that refers to the VPN's phase 1. To use this feature, do the following:

1. Go to **VPN > IPsec > Tunnels** and edit a tunnel.
2. Set **XAUTH Type** to **Auto Server**.
3. Set **User Group** to **Inherit Groups from Policy**.

This feature can be used for both interface-based and policy-based IPsec VPN phase 1s.

Syntax

```
config vpn ipsec {phase1 | phase1-interface}
   edit <name>
      set xauthtype auto
   end
end
```

Assigning Client IP Addresses Using the DHCP Proxy

IKE can now use the system DHCP proxy to assign client IP addresses.

To use this feature, the DHCP proxy must be enabled and a IP set. Up to 8 addresses can be selected for either IPv4 or IPv6. After the DHCP proxy has been configured, the `assign-ip-from` command is used to select assign IP address via DHCP.

Syntax

1. Enabling the DHCP proxy and setting an IP range.

```
config system settings
   set dhcp-proxy enable
   set dhcp-server-ip <IP_address>
   set dhcp6-server-ip <IP_address>
end
```

2. Setting the IPsec phase one to assign IP addresses using the DHCP proxy.

```
config vpn ipsec phase1
   edit <id>
      set assign-ip-from dhcp
   end
end
```

IP assignment can also come from a locally defined range or via the user group.

Transform Matching

FortiOS 5.2 supports combining multiple encryption, authentication, PRF, and DH transforms in a single IKEv2 proposal, which is used for selecting a transform set when the FortiGate unit is the responder. Each proposal now holds lists of transforms, instead of having just a single value per transform type. When negotiating, the proposal iterates over the transform lists to find a match.

Cookie Notification

Upon detecting that the number of half-open IKEv2 SAs is above the threshold value, the VPN dialup server will require all future SA_INIT requests to include a valid cookie notification payload that the server sends back, in order to preserve CPU and memory resources.

Message ID Sync for High Availability

IKE Message ID Sync is supported in FortiOS 5.2. Message ID Sync allows IKEv2 to re-negotiate send and receive message ID counters after a high availability fail over. By doing this, the established IKE SA can remain up, instead of re-initializing.

A diagnose command has also been added to show statistics for the number of HA messages sent/received for IKE: `diagnose vpn ike ha stats`.

Dynamic IPsec Route Control

Greater control has been added in FortiOS 5.2 concerning adding routes for IPsec VPN.

add-route

The `add-route` option is now available for all dynamic IPsec phase 1s and phase 2s, for both policy-based and route-base IPsec VPNs. This allows you to control the addition of a route to a peer destination selector.

This option was previously only available when `mode-cfg` was enabled in phase 1. Also, in phase 2, a new option has been added allowing `add-route` to automatically match the settings in phase 1.

This feature is enabled by default.

Syntax

1. Configuring phase 1:

```
config vpn ipsec {phase1 | phase1-interface}
   edit <name>
      set type dynamic
      set add-route {enable | disable}
   end
```

2. Configuring phase 2:

```
config vpn ipsec {phase2 | phase2-interface}
   edit <name>
      set add-route {phase1 | enable | disable}
   end
```

Blocking IPsec SA Negotiation

For interface-based IPsec, IPsec SA negotiation blocking can only be removed if the peer offers a wildcard selector. If a wildcard selector is offered then the wildcard route will be added to the routing information base with the distance/priority value configured in the phase1 and, if that is the route with the lowest distance, it will be installed into the forwarding information base.

In a case where this occurs, it is important to ensure that the distance value on the phase1 is set appropriately.

Default Lifetimes and Proposal Values

The default lifetimes for IKE and IPsec have been lengthened in FortiOS 5.2. The number of proposals has also increased and new default proposals have been created for Phase 1 and Phase 2. The changes are as follows:

- The default Phase1 lifetime is 86400 seconds (1 day).
- The default Phase2 lifetime is 43200 seconds (12 hours).
- The default Phase1 proposals are: aes128-sha256, aes256-sha256, 3des-sha256, aes128-sha1, aes256-sha1, and 3des-sha1.
- The default Phase2 proposals are: aes128-sha1, aes256-sha1, 3des-sha1, aes128-sha256, aes256-sha256, and 3des-sha256.
- The maximum number of proposals has been increased from 3 to 10.
- The default Diffie-Hellman (DH) group for phase1 and phase2 has changed from 5 to 14.

Prioritizing DH Group Configuration

In FOS 5.2, the default Diffie-Hellman DH group has changed from 5 to 14, to provide sufficient protection for stronger cipher suites that include AES and SHA2. Because of this change, both IKEv1 and IKEv2 now allow up to 3 DH groups to be configured in the phase 1 and phase 2 settings, while preserving the ordering since the initiator always begins by using the first group in the list. The default DH group in the configuration has been updated to include group 14 and 5, in that order. You can add and remove other groups and the order they appear in the configuration is the order in which they are negotiated.

The IKEv1 protocol does not natively provide for DH group negotiation in Aggressive Mode and Quick Mode. As a result, when multiple DH groups are used with IKEv1 Aggressive Mode or Quick Mode, delays in tunnel establishment can occur and so it is recommended to continue to configure matching DH groups on both peers whenever possible.

During negotiation with multiple DH groups, the new operation is as follows:

1. **IKEv1 Aggressive Mode Initiator:** Since Aggressive Mode includes the KE payload in the first message, FortiOS must select a group to use to generate the DH public number. FortiOS starts with the first group in the list. If the negotiation fails due to timeout, it will try the second group, and finally the third. If the third also fails, FortiOS goes back to the first DH group again, and starts over. Once it finds the correct group and the tunnel is established, it will continue to use that group for re-keying as long as the VPN connection remains up.
2. **IKEv1 Aggressive Mode Responder:** If the group proposed by the initiator doesn't match the group proposed by the responder, the negotiation fails due to no proposal chosen. Since authentication has not been established the responder cannot send a notify message to the initiator. The initiator will try the next DH group in its configuration when the negotiation time out occurs, which takes 30 seconds by default. At that point, if the next DH group is a successful match, the tunnel comes up.
3. **IKEv1 Main Mode Initiator:** In Main Mode, the SA and KE payloads come in different messages. The SA parameters, including DH group, are negotiated first in MM1 and MM2, then the KE payloads are exchanged in the MM3 and MM4 messages. So no change was made for Main Mode.
4. **IKEv1 Main Mode Responder:** As above, no change for Main Mode.
5. IKEv1 Quick Mode Initiator: Quick Mode has the same problem as Aggressive Mode, in that the SA proposal and KE payloads arrive in the same message. So unlike Main Mode, the initiator does not know the negotiated DH group prior to constructing its KE payload. Like with AM, it will start with the first group in the configured DH group list. If the negotiation times out, or if we receive a No-Proposal-Chosen notify message from the responder, we will switch to the next group in the list and try again.
6. IKEv1 Quick Mode Responder: Similar to Aggressive Mode, if the initiator's first group doesn't match, the Quick Mode will fail with a no proposal chosen error. In Quick Mode, you have the benefit of an authenticated IKE SA by which you can immediately notify the peer of the error. Sending the No-Proposal-Chosen notify to the initiator allows the initiator to try the next group immediately without waiting for a timeout.
7. **IKEv2 SA_INIT/CHILD_SA Initiator:** Like Aggressive Mode, in IKEv2 both the SA_INIT and CHILD_SA exchanges have the SA proposal and KE payload in the same message. However, unlike IKEv1, the IKEv2 RFC specifies a mechanism to handle this. In IKEv2, if the negotiated DH group does not match the group specified in the KE payload, the INVALID_KE notify message is sent and the initiator retries the exchange using the DH group specified in the notify message. Initiator side support for handling the INVALID_KE message has been added. This code wasn't needed previously, as the IKEv2 CLI allowed only one DH group to be configured. Now that the CLI restriction has been removed and multiple DH groups can be configured for IKEv2 in the phase1 and phase2 settings, the initiator will handle receipt of INVALID_KE messages as per the IKEv2 RFC. As long as the VPN connection remains up, the initiator will subsequently re-key using the negotiated group.
8. **IKEv2 SA_INIT/CHILD_SA Responder:** The responder side of our IKEv2 code already supports handling of the INVALID_KE message.

IPv6 Support for IPsec Phase 2

IPv6 support has been added to IPsec phase 2, allowing IPv6 firewall address and address groups to be used for phase 2 source and destination address types. The management of static selector rules has also been moved into the IKE daemon, allowing named selectors to be reloaded if any named address or address groups are changed, without requiring the FortiGate unit to be rebooted before changes are applied.

IPsec VPN Support with the FortiController-5103B

The FortiController-5103B can now learn the routing table as a slave to receive the update from master. When packets are received, the 5103B blade tests the routing table to determine whether the traffic will be routed to the IPsec interface, if it does, it will trigger 5103 to forward the traffic to dedicated IPsec blade. This ensures that all IPsec traffic is sent to the dedicated IPsec blade, even traffic originating from the 5000 system, such as monitoring systems or internal emails.

SSL VPN

New SSL VPN features include:

- SSL VPN Configuration
- ECDSA Local Certificates
- Host Security Check Error Replacement Message

SSL VPN Configuration

Several changes have been made to how SSL VPNs are created and configured.

VPN Settings

The SSL VPN settings page, found at **VPN > SSL > Settings**, has been reorganized to be more intuitive. The settings are now found in the following sections:

- **Connection Settings** define how users connect and interact with an SSL VPN portal. This section includes Listen on Interface(s), Idle Logout, and Server Certificate.
- **Tunnel Mode Client Settings** define the settings that clients will receive upon connecting to the VPN. This section includes Address Range and Allow Endpoint Registration.
- **Authentication/Portal Mapping** allows you to define different portals to different users and groups.

VPN Portal

New options for split tunneling have been added to SSL VPN portals, which are configured by going to **VPN > SSL > Portals,** including a routing address and a tunnel mode for IPv6. These options can also be configured in the CLI, using the command `config vpn ssl web portal`.

Creating the Firewall Policy

When creating a firewall policy for your SSL VPN, you will select ssl.root as the **Incoming Interface**. Also, source devices are not applicable to SSL VPN firewall policies.

For more information about using a virtual WAN link, please see the FortiGate Cookbook recipe SSL VPN for Remote Users.

ECDSA Local Certificates

The use of ECDSA Local Certificates for SSL VPN Suite B support is now supported. This will allow the following:

1. Importing ECDSA certificate.
2. Generating ECDSA certificate requests.
3. Using ECDSA certificate in SSL VPN.
4. Using ECDSA certificate in web-based manager.

ECDSA certificates can be generating using the following command in the CLI: `exec vpn certificate local generate ec`.

RSA certificates are now generated using the following command:

```
exec vpn certificate local generate rsa.
```

Host Security Check Error Replacement Message

The replacement message that now appears when an SSL VPN host security check fails can now be customized using the CLI.

Syntax

```
config system replacemsg sslvpn hostcheck-error
   set buffer <string>
   set header {none | http | 8bit}
   set format {none | text | html}
end
```

Authentication

New authentication features include:

- Captive Portal
- User Authentication via a POP3 Server
- Limiting Guest User Accounts
- Nested Group Search in LDAP Authentication
- Password Length for User Authentication
- Certificates for Policy Authentication
- Authentication Blackouts
- Single Sign-On for Guest Accounts

Captive Portal

There have been several changes made to authentication using a captive portal. Additional captive portal options have also been added for wireless networks. For more information, see Captive Portal for WiFi on page 142.

External Captive Portals

An external captive portal can be used to configure each FortiGate interface as an independent, external web URL. To configure an interface, go to **System > Network > Interfaces** and edit the desired interface. Select **Captive Portal** as the **Security Mode**, then set **Authentication Portal** to **External** and configure the other settings as required.

Once a client has been authenticated by the portal, by default they will be sent to original URL that was requested. The portal can also be configured to send the client to a hard coded URL that contains a replacement message.

Syntax

In the following example, the LAN interface is configured with external captive portal that has a specified URL (http://10.6.2.218/?Auth=Success) to redirect clients to after successful authentication.

```
config system interface
   edit "lan"
      set security-mode captive-portal
      set security-external-web "http://10.6.2.218/portal"
      set security-redirect-url "http://10.6.2.218/?Auth=Success"
      set security-groups "rug1"
   end
```

Using Groups from the Security Policy

Portal interfaces can now be configured to use the user groups set in the security policies. This will happen by default if no user group is configured on the interface.

Exempting a Policy

Security policies can now be exempt from captive portals, using the command `captive-portal-exempt enable`.

Replacement Messages

The captive portal-specific replacement messages have been removed. Authentication replacement messages will be used for portals.

User Authentication via a POP3 Server

A POP3 server can now be used to verify user credentials when they authenticate through a web portal or any supported authentication method.

The following maximum values are associated with POP3 authentication:

- A maximum of 10 pop3/pop3s servers can be defined per box
- A single user group can have up to a pool of 6 POP3 servers assigned

POP3 authentication can be configured using the CLI:

Configuring a POP3 user

```
config user pop3
   edit name
      set server "pop3.fortinet.com"
      set secure {starttls | pop3s | none}
      set port 110
   end
```

Configuring a POP3 user group

```
config user group
   edit pop3_grp1
      set member "pop3_server1" "pop3_server2"
   end
```

Limiting Guest User Accounts

A new option to has been added to the guest user group where the administrator can restrict the maximum number of guest accounts that can be created. After the limit is reached, the portal administrator will need to remove some expired accounts. The number of accounts can be set from 1-1024 or left as unlimited (0 in the CLI), which is the default setting.

In the web-based manager, the lower limit is restricted if there are existing group members. In order to set a lower number, guest accounts must be removed prior to the limit being set.

Syntax

```
config user group
   edit guest-group
```

```
      set group-type guest
      set max-accounts [0-1024]
   end
```

Nested Group Search in LDAP Authentication

Nested group search is a new feature added to Windows AD server when the LDAP server's settings have `group-member-check` set to `user-attr`. After authentication succeeds, `fnbamd` gets groups from user attributes and repeats LDAP queries on the groups until reaches the top layer.

Syntax

```
config user ldap
   edit <ldap-server-name>
      set search-type nested
   end
```

Password Length for User Authentication

In FortiOS 5.2, the length for all passwords connected to user authentication features has been changed to support a maximum of 128 characters.

Certificates for Policy Authentication

The CA certificate used for policy authentication can now be configured, instead of being restricted to the built-in Fortinet certificate. By doing this, the authenticated user can be presented with a certificate that is already trusted by their browser and certificate errors can be avoided.

Syntax

```
config user setting
   set auth-ca-cert <name>
end
```

Authentication Blackouts

If five failed logins are made from an IP within one minute, the IP is put on a blackout list. Future logins from this IP are rejected as long as the IP is on this list. The IP remains on the blackout list for auth-blackout-time seconds. The amount of time an IP is blacklisted can be configured through the CLI:

Syntax

```
config user setting
   set auth-blackout-time 300
end
```

This feature only applies to IP-based authentication schemes.

Single Sign-On for Guest Accounts

The default **FSSO_Guest_Users** group has changed to **SSO_Guest_Users**. This group supports guests using both Fortinet Single Sign-On (FSSO) and RADIUS Single Sign-On (RSSO). Users can also now be added to this group SSO_Guest_group using the CLI.

Syntax

```
config user group
   edit SSO_Guest_group
      set member <names>
   end
end
```

Managing Devices

New device management features include:

- On-Net Status for FortiClient Devices
- Endpoint Licenses
- URL Filter Lists in Endpoint Control
- FortiGuard Categories Consistency with FortiClient
- Default Device Groups
- Device Detection for Traffic Not Flowing Through the FortiGate

On-Net Status for FortiClient Devices

The **Online** column of the FortiClient Monitor has been changed to **Status**. This column will show the current status of the device, and whether or not it is registered.

Two of the possible status options are on-net or off-net. In order to record this information, the DHCP server must be enabled for FortiClient On-Net Status. In order to determine if a FortiClient device is on or off net, a DHCP cookie is sent to FortiClient that contains the FortiGate's serial number. FortiClient will then compare that serial number to the number for the FortiGate it is registered with. If they match, the FortiClient will be considered on-net.

In configurations using high availability, the cookie contains the serial number of all cluster members.

This status has also led to the following options have been added to FortiClient profiles:

- Client Web Filtering when On-Net: when enabled, web filtering is applied to FortiClient traffic even when it is protected by a FortiGate unit.
- Auto-connect when Off-Net: This option allows the FortiClient to autoconnect to a VPN even when it has an off-net status.
- Client-based Logging when On-Net: when enabled, the FortiClient will continue to log even when its traffic is flowing through a FortiGate unit.

Endpoint Licenses

New Endpoint licenses are now available in FortiOS 5.2. Information about the status of the current license can be found in the FortiClient section of the **License Information** widget.

The following licenses will be available:

- **Desktop models and FortiGate-VM00:** 200 clients
- **1U models, FortiGate-VM01 and FortiGate-VM02:** 2,000 clients
- **2U models and FortiGate-VM04:** 8,000 clients
- **3U models, FortiGate-ATCA, and FortiGate-VM08:** 20,000 clients

Because the new licenses are for one year, the activation method has changed. New licenses are purchased similarly to a FortiGuard service, with no further registration of the license required. The device can then be registered with the FortiGate unit.

If the device does not have access to Internet, you can download the license key from support site and manually upload it to your FortiGate. The license will be for that specific device and will have an license expiry date.

While the older licenses from FortiOS 5.0 will still be supported, they will have the following limitations:

- The On-Net Status feature will not be supported.
- Logging options will only appear in the CLI.
- FortiAnalyzer Support for logging and reporting will be limited.
- You will not be able to enter any v5.0 license keys.

URL Filter Lists in Endpoint Control

URL filters can now be sent to devices running FortiClient that connect to the FortiGate unit. All URL filter types (Simple/Regex/Wildcard) and actions (Allow/Block/Exempt/Monitor) can be deployed to FortiClient

Upon receiving the URL filter list, FortiClient will save and display the received URL filter list in the web-based manager.

If the URL list is later changed or removed from the FortiGate unit, these changes will also appear in FortiClient.

FortiGuard Categories Consistency with FortiClient

If FortiGuard categories are disabled on a FortiGate unit, they will now also be disabled in FortiClient for managed devices, even if FortiGuard categories were used previously.

Default Device Groups

The predefined device groups have been changed to the following:

- Windows PC (includes Windows servers and computers but not tablets or phones)
- Mac
- Linux
- Printer
- Mobile devices (includes tablets and phones from all vendors)
- VoIP phones
- Router/firewall/gateway devices (does not include switch devices)
- Other (for unknown devices)

To improve accuracy, device types are now identified using UIDs instead of MAC addresses.

Device Detection for Traffic Not Flowing Through the FortiGate

In FortiOS 5.2, any traffic hitting a FortiGate interface, regardless of whether it is going to be dropped, forwarded or processed locally, will be used by device detection, allowing devices to be detected even if their traffic does not flow through the FortiGate unit. This includes traffic that hits an interface with IPS sniffer mode enabled, as well as broadcast and multicast traffic.

Wireless Networking

New wireless networking features include:

- FortiAP Management
- Captive Portal for WiFi
- New Wireless Health Charts
- RADIUS Accounting
- 802.11ac and DARRP Support
- Date Channel DTLS in Kernel

FortiAP Management

How FortiAP units are managed by a FortiGate unit has changed in several ways.

Manually Selecting AP Profiles

AP profiles are no longer assigned automatically. Instead, a default or custom profile must be chosen when the connection to the FortiAP unit is configured.

The **Background Scan** option has also been replaced by **Spectrum Analysis** (for more information, see New Wireless Health Charts) and either 20MHz or 40MHz must be selected for Radio 1's channel width.

You can choose to override some options set in the profile for a particular FortiAP unit. To do this, go to **WiFi Controller > Managed Access Points > Managed FortiAPs** and, under **Wireless Settings**, select **Override Settings**. This allows you to change WiFi radio settings, including SSIDs, TX power, and rogue AP scanning. This can also be configured in the CLI:

Syntax

```
config wireless-controller wtp
   edit <name>
      set override-profile enable
   end
end
```

AP Scanning

AP scanning, including rogue AP detection, is now part of WIDS Profiles. It can be found by going to **WiFi Controller > WiFi Network > WIDS Profiles**. It can also be configured through the CLI:

Syntax

```
config wireless-controller wids-profile
   edit 0
      set ap-scan {enable | disable}
      set ap-bgscan-period <interval>
      set ap-bgscan-intv <interval>
      set ap-bgscan-duration <interval>
      set ap-bgscan-idle <interval>
      set ap-bgscan-rpot-intv <interval>
```

```
      set ap-bgscan-disable-day <day>
      set ap-fgscan-repot-intv <interval>
      set rogue-scan {enable | disable}
    end
end
```

Radio Settings Summary

The Radio Settings Summary table can be found by going to **WiFi Controller > Managed Access Points > Managed FortiAPs** and editing a FortiAP unit. The table shows information on the FortiAP unit's Radio 1 and 2 (if applicable), including settings, channels, and SSIDs.

CLI Console Access

The CLI console on a FortiGate unit can now be used to connect directly to a managed FortiAP unit that has been configured to enable login-enable. To access the FortiAP, use the command `execute telnet <ip>`, using the IP address of the FortiAP.

Telnet must be used, as FortiAPs do not support SSH/HTTPS admin access.

The console can also now be accessed by going to **WiFi Controller > Managed Access Points > Managed APs** and selecting the option **Connect to CLI**. The console will appear in a pop-up window.

If `login-enable` is set to `default` or `disable` on the FortiAP unit, or the FortiAP is offline, this option will not appear.

Split Tunneling for Wireless Traffic

Split tunneling can now be used for wireless traffic, allowing you to optimize WiFi traffic flow by directing only corporate traffic back to the FortiGate unit's wireless controller, while local application traffic remains local. With split tunneling, a remote user associates with a single SSID, can get access to corporate resources (for example, a mail server) and local resources (for example, a local printer).

Split tunneling should be only used for SSIDs in tunnel mode.

Syntax

1. Enabling split tunnelling for an SSID.

```
config wireless-controller vap
   edit <name>
      set split-tunneling enable
   end
end
```

2. Setting the IP lists for split tunneling

```
config w-c {wtp-profile | wtp}
   set split-tunneling-acl-local-ap-subnet enable
   config split-tunneling-acl
      edit <ID>
```

```
            set id <ID>
            set dest-ip <IP_address>
        end
    end
```

Captive Portal for WiFi

Several changes have been made for captive portal security on wireless networks. Wireless captive portals can also use the new features for all captive portals described in "Authentication" on page 134.

New Configuration Options

The following options can now be configured for captive portals that use wireless interfaces:

- Security exempt list names can be added to a captive portal. This option is only available when user groups are selected as part of the SSID configuration, rather than being a match for groups in the security policy.
- URL redirection is available after the disclaimer/authentication screen.
- Four types of portals are available: authentication, authentication with disclaimer, disclaimer only, or email collection. When the mode is email collection or disclaimer only, the options for setting user groups or having an external captive portal are not available.

Syntax

```
config wireless-controller vap
   edit <name>
      set security captive-portal
      set portal type {auth | auth+disclaimer | disclaimer | email-collect}
      set security-exempt-list <name of list>
   end
end
```

WPA Personal Security + Captive Portal

A new option has also been added that uses WPA Personal security as well as a captive portal. This option also allows groups to be imported from the policy.

New Wireless Health Charts

Two new charts have been added to the Wireless Health Monitor showing spectrum analysis information on the sources of wireless interference.

In order for these widgets to appear, spectrum analysis must first be enabled. This is done by editing the AP profile used by your FortiAP units and selecting **Spectrum Analysis** for all applicable radios.

Spectrum analysis can also be enabled in the CLI.

Syntax

```
config wireless-controller wtp-profile
   edit <name>
      config <radio>
         set spectrum-analysis enable
      end
   end
end
```

After spectrum analysis has been enabled, view the **Top Wireless Interference** widget found in the Wireless Health Monitor. A chart icon will appear in the **Channel** column. Selecting this icon will open the new WiFi charts: **Spectrum Analysis** and **Top Wireless Interference**.

The **Spectrum Analysis** chart shows WiFi signal interference as detected by a particular FortiAP.

The **Top Wireless Interference** chart shows SSIDs that are interfering with a particular FortiAP unit.

RADIUS Accounting

RADIUS accounting is now supported for wireless networks, allowing RADIUS accounting messages to be sent that contain a wireless user's name and IP address.

If an accounting server has been enabled for RADIUS, the wireless client information will be sent to it.

802.11ac and DARRP Support

802.11ac support has been added for FortiOS 5.2, allowing a FortiGate unit to manage FortiAP models 221C and 320C. Distributed Automatic Radio Resource Provisioning (DARRP) is also supported for 802.11ac radio.

Syntax

```
config wireless-controller wtp-profile
   edit {fap221c | fap320c}
      config radio-2
         set darrp enable
      end
end
```

Date Channel DTLS in Kernel

Data channel Datagram Transport Layer Security (DTLS) can now be enabled in kernel using the CLI.

Syntax

```
config wireless-controller wtp-prof
   edit wtpprof
      set dtls-in-kernel enable
   end
end
```

IPv6

New IPv6 features include:

- IPv6 Address Ranges
- TCP MSS Values
- RSSO Support
- FortiManager Connections
- Geographical Database

IPv6 Address Ranges

IPv6 address ranges can now be created, using either the web-based manager or the CLI.

Syntax

```
config firewall address6
   edit <name>
      set type iprange
      set start-ip <address>
      set end-ip <address>
   end
end
```

TCP MSS Values

TCP MSS values for both the sender and the receiver can now be set for IPv6 policies using the CLI.

Syntax

```
config firewall policy6
   edit <index_int>
      set tcp-mss-sender <value>
      set tcp-mss-receiver <value>
   end
end
```

RSSO Support

RADIUS Single Sign-On (RSSO) is supported in IPv6 and can be configured in the CLI. Fallthrough for unauthenticated

Syntax

```
config firewall policy6
   edit <id>
      set rsso enable
      set fall-through-unauthenticated enable
   end
end
```

FortiManager Connections

IPv6 can now be used to connect a FortiGate unit to a FortiManager unit.

Geographical Database

An IPv6 geographical database has been added to properly identify the geographical locations of traffic in reports.

High Availability

New high availability features include:

- DHCP and PPPOE Support for Active-Passive Mode
- VRRP Support
- Trigger Failover
- Synchronizing a GTP Tunnel over Physical Ports
- IPv6 Management Interface Gateway

DHCP and PPPOE Support for Active-Passive Mode

High Availability is now supported in Active-Passive mode when there are interfaces working in DHCP client or PPPOE client mode.

VRRP Support

Additional features have been added to support Virtual Router Redundancy Protocol (VRRP).

VRRP Groups

A VRRP group includes all the relevant VRRP IDs and tracks the VRRP status in order to force the status of all group members if a VRRP domain is changed from master to backup.

VRRP groups are configured through the CLI. The VRRP group ID can be between 1 and 65535.

Syntax

```
config system interface
   edit <port>
      config vrrp
         edit <id>
            set vrgrp <id>
         end
   end
```

A **VRRP** column has also been added to the interfaces list in the web-based manager that will show the VRRP ID, group, and status. This list can be found at **System > Network > Interfaces**.

Using a Second Destination IP (VRDST)

VRRP can now be configured with second destination IP (VRDST) for monitoring. When two IPs are used, VRRP failure will only be reported if both monitored IPs are down. A second VRDST can be configured using the CLI.

Syntax

```
config system interface
   edit <interface>
      config vrrp
         edit <id>
```

```
            set vrdst <ip1> <ip2>
        end
    end
```

Trigger Failover

HA failover can now be enabled and disabled using the following CLI commands:

- `diagnose sys ha set-as-master enable`: immediately enables the local FortiGate unit as the HA master.
- `diagnose sys ha set-as-master disable`: immediately disables this mode. Optionally, a time frame can be added after `disable`, which will disable the mode at the appointed time. The time format is yyyy-mm-dd hh:mm:ss.

Synchronizing a GTP Tunnel over Physical Ports

In order to properly handle GPRS Tunneling Protocol (GTP) synchronization under high stress loads, FortiOS 5.2 will use the interfaces set in `set session-sync-dev` (part of `config system ha`) to allow GTP tunnels to synchronize directly over physical ports when both the HA primary and secondary are up. A new diagnose command, `diagnose firewall gtp hash-stat`, has also been added to display GTP hash stat separately.

IPv6 Management Interface Gateway

IPv6 management interface gateways are now supported in FortiOS 5.2.

Syntax

```
config system ha
   set ha-mgmt-interface-gateway6 <IPv6_address>
end
```

WAN Optimization, Web Cache, and Explicit Proxy

New WAN optimization, web cache, and explicit proxy features include:

- Explicit Proxy Policy Table - for explicit web proxy, explicit FTP proxy and WAN optimization policies
- Distributing Explicit Web Proxy Traffic to Multiple CPU Cores
- Proxy Header Control
- Explicit Web Proxy SOCKS services support for TCP and UDP traffic
- Preventing the explicit web proxy from changing source addresses
- Explicit web proxy firewall address URL patterns

Explicit Proxy Policy Table - for explicit web proxy, explicit FTP proxy and WAN optimization policies

Explicit proxy policies now have a dedicated table and creation page, found at **Policy & Objects > Policy > Explicit Proxy**. The corresponding CLI command is:

```
config firewall explicit-proxy-policy
```

You use explict proxy policies to add policies for the IPv4 and IPv6 explicit web proxy and for the explicit FTP policy. The first step in creating an explicit proxy policy is to select the proxy type (web or FTP). The options availabl e then depend on the explicit proxy type.

From the CLI you use the explicit web proxy policy to add WAN optimization tunnel policies. In FortiOS 5.0 you added WAN optimization tunnel policies by setting the source interface to wanopt. In FortiOS 5.2 you create an explicit web proxy policy from the CLI and set the proxy type to wanopt. For example:

```
configure firewall explicit-proxy-policy
   edit 0
      set proxy wanopt
      set dstintf internal
      set srcaddr all
      set dstaddr server-subnet
      set action accept
      set schedule always
      set service ALL
   next
end
```

Distributing Explicit Web Proxy Traffic to Multiple CPU Cores

To improve explicit web proxy performance, FortiOS 5.2 distributes explicit web proxy processing to multiple CPU cores. By default web proxy traffic is handled by half of the CPU cores in a FortiGate unit, so if your FortiGate unit has 4 CPU cores, by default two will be used for explicit web proxy traffic. You can increase or decrease the number of CPU cores that are used in the CLI.

```
config system global
   set wad-worker-count <number>
end
```

The value for <number> can be anything between 1 and the total number of CPU cores in your FortiGate unit. The default value for <number> is half the number of CPU cores in your FortiGate unit.

Proxy Header Control

You can create explicit web proxy profiles that can add, remove and change HTTP headers. The explicit web proxy profile can be added to a web explicit proxy policy and will be applied to all of the HTTP traffic accepted by that policy.

You can change the following HTTP headers:

- client-ip
- via header for forwarded requests
- via header for forwarded responses
- x-forwarded-for
- front-end-https

For each of these headers you can set the action to:

- Pass to forward the traffic without changing the header
- Add to add the header
- Remove to remove the header

You can also configure how the explicit web proxy handles custom headers. The proxy can add or remove custom headers from requests or responses. If you are adding a header you can specify the content to be included in the added header.

Create web proxy profiles from the CLI:

```
config web-proxy profile
   edit <name>
      set header-client-ip {add | pass | remove}
      set header-via-request {add | pass | remove}
      set header-via-response {add | pass | remove}
      set header-x-forwarded-for {add | pass | remove}
      set header-front-end-https {add | pass | remove}
         config headers
            edit <id>
               set action {add-to-request | add-to-response | remove-from-request |
                   remove-from-response}
               set content <string>
               set name <name>
            end
      end
```

Use the following command to add a web proxy profile to an explicit proxy policy:

```
config firewall explicit-proxy-policy
   edit <id>
      set webproxy-profile <name>
   end
```

Explicit Web Proxy SOCKS services support for TCP and UDP traffic

You can now configure Web Proxy services to allow UDP traffic as well as TCP traffic to be accepted by the SOCKS proxy. Previously, the web proxy would only accept TCP SOCKS traffic.

Web proxy services can be configured in the CLI.

Syntax

Use the following command to create a custom service for UDP traffic over the SOCKS proxy:

```
config firewall service custom
   edit <name>
      set explicit-proxy enable
      set category Web\ Proxy
      set protocol SOCKS-UDP
      set tcp-portrange 8080-8080
   end
end
```

The option to create a custom service for TCP traffic over the SOCKS proxy has also changed. For example, use the following command to create a custom service for TCP traffic over the SOCKS proxy:

```
config firewall service custom
   edit <name>
      set explicit-proxy enable
      set category Web\ Proxy
      set protocol SOCKS-TCP
      set tcp-portrange 80-80
   end
end
```

Preventing the explicit web proxy from changing source addresses

By default in NAT/Route mode the explicit web proxy changes the source address of packets leaving the FortiGate to the IP address of the FortiGate interface that the packets are exiting from. In Transparent mode the source address is changed to the management IP.

This configuration hides the IP addresses of clients and allows packets to return to the FortiGate unit interface without having to route packets from clients. You can use the following command to configure the explicit web proxy to keep the original client's source IP address:

```
config firewall explicit-proxy-policy
   edit 0
      set proxy web
      set transparent enable
   end
```

Explicit web proxy firewall address URL patterns

You can add URL pattern addresses and address groups to control the destination URLs that explicit web proxy users can connect to. To add a URL pattern to go to **Policy & Objects > Objects > Addresses**, select **Create New** and set the Type to **URL Pattern (Explicit Proxy)**. Add a URL or URL pattern that defines the URL or URLs that explicit proxy users should be limited to. Set the **Interface** to **any**.

For example to limit access to a single website:

www.fortinet.com

To limit access to websites from the same domain:

google.com

To limit access to a part of a website:

www.apple.com/ipad/

To add a URL pattern group, create several URL pattern addresses then go to **Policy & Objects > Objects > Addresses**, select **Create New > Group** and add URL patterns to the address group.

Then when creating explicit web proxy policies, select the URL pattern addresses or groups as the destination address.

URL patterns and HTTPS scanning

For HTTPS traffic, URL patterns can only be matched up to the root path. For example, consider the following URL pattern:

www.apple.com/ipad/

If a proxy user browses using HTTP, this URL pattern limits their access the iPad pages of www.apple.com. However, if a proxy user browses using HTTPS, they will be able to access all pages on www.apple.com.

Advanced Routing

New advanced routing features include:

- BGP Neighbor Groups
- OSPF Fast Hello
- BGP Conditional Advertising
- Source and Destination IP-based Mode for ECMP
- Policy Routes

BGP Neighbor Groups

A Border Gateway Protocol (BGP) neighbor group can now be configured automatically based on a range of neighbors' source addresses, rather than configuring neighbors individually. A maximum number of neighbors can be set for each group to be between 1 and 1000.

Syntax

```
config router bgp
   config neighbor-group
      edit <name>
         set ... (same configuration options as config neighbor)
   next
   config neighbor-range
      edit <id>
         set prefix <class_ip&net_netmask>
         set max-neighbor-num <integer>
         set neighbor-group <name>
      end
end
```

OSPF Fast Hello

Open Shortest Path First (OSPF) fast hello provides a way to send a set number of hello packets per second and use a dead interval of four hellos. Fast hello can be configured on an OSPF interface through the CLI. If `dead-interval` is set to 1 second, fast hello will be enabled. The `hello-multiplier` value, which can be between 4 and 10, sets the number of hello packets that will be sent per second.

Syntax

```
config ospf-interface
   edit ospf1
      set interface port1
      set network-type broadcast
      set dead-interval 1
      set hello-multiplier 4
   end
end
```

BGP Conditional Advertising

BGP conditional advertising is supported in FortiOS 5.2.

Normally, routes are propagated regardless of the existence of a different path. Using BGP conditional advertisement allows a route not to be advertised based on existence or non-existence of other routes. With this new feature, a child table under bgp neighbor is introduced. Any route matched by one of the route-map specified in the table will be advertised to the peer based on the corresponding condition route-map.

Syntax

```
config router bgp
   config neighbor
      edit <name>
         set remote-as 3
         config conditional-advertise
            edit <name>
               set condition-routemap <name>
               set condition-type {exist | non-exist}
            end
         end
      end
   end
end
```

Source and Destination IP-based Mode for ECMP

A new mode has been added that allows Equal-cost multi-path routing (ECMP) to select next hop based on both source and destination IPs. This can be configured as a global setting (if `virtual-wan-link` is disabled) or for a virtual WAN link.

Syntax

```
config system {settings | virtual-wan-link}
   set v4-ecmp-mode source-dest-ip-based
end
```

Policy Routes

The following options have been added for policy routes:

- Multiple source/destination subnets.
- Multiple input devices.
- `src-negate` and `dst-negate` can now be enabled.
- `action` can now be set to `permit` or `deny`.

Logging and Reporting

New logging and reporting features include:

- Traffic and UTM Logging Improvements
- FortiGate Daily Security Report
- GTP Logging Improvements
- Flash-based Logging Disabled on Some Models
- Accessing Policy-specific Logs from the Policy List
- IPS Event Context Data in Log Messages
- Sniffer Traffic Log
- Selecting Sources for Reports
- Threat Weight
- Disk Usage Information in System Event Logs
- Event Log Generated When a Crash Occurs
- Displaying FortiFlow Names

Traffic and UTM Logging Improvements

Traffic and UTM Logging has been simplified in FortiOS 5.2 by making the following changes:

- Removing all overlapping fields between the UTM Logs and Traffic Logs, with the exception of the common fields `sessionid`, `vd`, `user`, and `group`, and application control critical info, which will be present in both the Traffic Log and Application log.
- Fields have been renamed so that they are the same in all logs.
- Some rarely used fields were removed; for example, `profiletype`.
- The `action` field reflects the Firewall action (accept or deny). This will allow you to see from the traffic logs if the session was allowed or blocked and whether it was allowed or blocked by the firewall or by a security feature. If it was a security feature, you will need to look at the UTM logs to determine which feature blocked the traffic.
- The field `utmaction` is set to the most severe actions across all security features. The severity from highest to lowest is: Block, Reset, Traffic Shape, Allow.
- You can now drill-down from a traffic log to its corresponding UTM logs.
- `extended-utm-log` and `log` options for security profiles have been removed.
- Log roll logic have been rewritten so that traffic log file and related utm log files are rolled together. Uploadd will pack these files together to send to a FortiAnalyzer unit.
- An anomaly log category has been added to separate anomaly logs from IPS logs.

FortiGate Daily Security Report

The FortiGate UTM Security Analysis Report has been renamed the FortiGate Daily Security Report.

A variety of other changes have also occurred to the report:

- A new cover page has been added that contains the report name, date, date range, and device name.
- A table of contents page has been added.

- The information VPN usage now shows all use, rather than just a top 10 list. This allows a complete list to be shown that includes all tunnels for Site-to-Site IPsec VPNs and all users for dial-up IPsec VPN tunnels, SSL VPN tunnels, and SSL VPN web mode. Information on connection time has also been added.
- Entries will not be displayed when there is a zero bandwidth/or connection time.

GTP Logging Improvements

Several changes have been made concerning GPRS Tunneling Protocol (GTP) and logging.

GTP-U Logging

FortiOS 5.2 supports GPRS Tunnelling Protocol User Plane (GTP-U) logging for both forwarded and dropped packets at the kernel level. FortiGate log entries now contain International Mobile Subscriber Identity (IMSI), Mobile Subscriber Integrated Services Digital Network-Number (MSISDN), Access Point Name (APN), and header Tunnel Endpoint Identifier (TEID) if available/applicable.

Three new CLI commands are added to GTP profile for GTP-U logging:

- `gtpu-forwarded-log`: Enable/disable logging of forwarded GTP-U packets.
- `gtpu-denied-log`: Enable/disable logging of denied GTP-U packets.
- `gtpu-log-freq`: Sets the logging frequency of GTP-U packets.

Syntax

```
config firewall gtp
   edit gtp_profile
      set gtpu-forwarded-log enable
      set gtpu-denied-log enable
      set gtpu-log-freq 10
   end
end
```

The log frequency value is per number of packets, for example `set gtpu-log-freq 10` means the FortiGate unit should have a log entry per 10 packets.

GTP Event Log

A new GTP event log has been added, which can be found by going to **Logging & Reports > Event Log > GTP**. This log will show GTP activity status and a Deny Cause for any traffic that was blocked or dropped.

In order to see this log, it must be enabled either in the Log Settings or in the CLI.

Syntax

```
config log eventfilter
   set gtp enable
end
```

Flash-based Logging Disabled on Some Models

On some FortiGate models, flash-based logging is not available in FortiOS 5.2. For these platforms, Fortinet recommends the free FortiCloud central logging & reporting service, as it offers higher capacity and extends the features available to the FortiGate.

For a full list of affected models, please refer to the Release Notes.

Accessing Policy-specific Logs from the Policy List

In FortiOS 5.2, the log viewer can be opened directly from the policy table, with filters applied automatically to show only the logs relating to that policy. To view these logs, right-click on the **Seq.#** column for the policy and select **Show Matching Logs**.

The log viewer will filter using the Policy UUID if it is enabled. If not, the Policy ID will be used.

IPS Event Context Data in Log Messages

Attack context logging can now be enabled for an IPS sensor, which will add two new fields, `attackcontext` and `attackcontextid`, into an attack log.

The `atkctx` field in log will output BASE64 encoded string of:

```
<PATTERNS> trigger patterns separated by ';' </PATTERNS> <URI> uri buffer </URI>
    <HEADER> header buffer </HEADER> <BODY> body buffer </BODY> <PACKET> packet
    buffer </PACKET>"
```

`Attackcontext` entries longer than 1KB is split in multiple log entries, which share the same `incidentserialno`. `Attackcontextid` will help identify these segment by showing what order they have in the sequence; for example, `<1/3>` means this log is the first segment of a log message containing three segments in total.

Sniffer Traffic Log

Forward traffic from a FortiGate unit that is in one-arm sniffer mode can now be logged on that FortiGate unit. To log this traffic, the appropriate logging option must be selected for the sniffer interface.

Logging information can be viewed in the new sniffer log, which can be found by going to **Log & Report > Forward Traffic > Sniffer Traffic**.

Selecting Sources for Reports

The source for reports can now be configured to be either forward traffic, sniffer traffic, or both.

Syntax

```
config report setting
   set status enable
   set report-source {forward-traffic | sniffer-traffic | both}
end
```

Threat Weight

The 5.0 feature client reputation has been renamed Threat Weight in FortiOS 5.2 and has been moved from Security Profiles to **Log & Report > Log Config > Threat Weight**. It can now be configured in the CLI using the command `config log threat-weight`.

Disk Usage Information in System Event Logs

Disk usage information will now be included in system event logs for FortiGate models that have a hard disk.

Event Log Generated When a Crash Occurs

A brief event log will now be generated when a crash occurs with brief information about the crash.

Displaying FortiFlow Names

Object name data will now be pulled from FortiFlow in applicable locations, including the **Forward Traffic** log and the **Top Destinations** widget.

Other New Features

Other new features in FortiOS 5.2 include:

- SIP Traffic is Handled by the SIP ALG by Default
- Changing the Header Name of Load Balanced HTTP/HTTPS Traffic
- TOS and DSCP Support for Traffic Mapping

SIP Traffic is Handled by the SIP ALG by Default

Previous versions of FortiOS used the SIP session helper for all SIP sessions. You had to remove the SIP session helper from the configuration for SIP traffic to use the SIP ALG.

In FortiOS 5.2, all SIP traffic is now processed by the SIP ALG by default. You can change the default setting using the following command:

```
config system settings
   set default-voip-alg-mode {proxy-based | kernel-helper-based}
end
```

The default is `proxy-based`, which means the SIP ALG is used. If set to `kernel-helper-based`, the SIP session helper is used. If a SIP session is accepted by a firewall policy with a VoIP profile, the session is processed using the SIP ALG even if `default-voip-alg-mode` is set to `kernel-helper-based`.

If a SIP session is accepted by a firewall policy that does not include a VoIP profile:

- If `default-voip-alg-mode` is set to `proxy-based`, SIP traffic is processed by the SIP ALG using the default VoIP profile.
- If `default-voip-alg-mode` is set to `kernel-helper-based`, SIP traffic is processed by the SIP session helper. If the SIP session help has been removed, then no SIP processing takes place.

Changing the Header Name of Load Balanced HTTP/HTTPS Traffic

A header name can now be configured for HTTP and HTTPS traffic that flows through a virtual server, rather than using the default X-Forward-For header.

In order to use this feature, the HTTP IP header must be enabled.

Syntax

```
config firewall vip
   edit <name>
      set type server-load-balance
      set server-type {http | https}
      set http-ip-header enable
      set http-ip-header-name <name>
   end
end
```

TOS and DSCP Support for Traffic Mapping

Both TOS and DSCP are now supported for traffic mapping but only one method can be used at a time, with TOS as the default. The type used and its other attributes can be configured through the CLI.

Syntax

```
config system global
   set traffic-priority {tos | dscp}
   set traffic-priority-level {low | medium | high}
end
```

RFC List

The following RFCs are supported by the new features in FortiOS 5.2:

Number	Title
791	Internet Protocol
1349	Type of Service in the Internet Protocol Suite
1925	The Twelve Networking Truths
2516	A Method for Transmitting PPP Over Ethernet (PPPoE)
4754	IKE and IKEv2 Authentication Using the Elliptic Curve Digital Signature Algorithm (ECDSA)
4787	Network Address Translation (NAT) Behavioral Requirements for Unicast UDP
5996	Internet Key Exchange Protocol Version 2 (IKEv2)

Chapter 2 - Getting Started

This guide contains the following sections:

- Differences between Models examines key types of differences between FortiGate models.
- Installation contains information about installing a FortiGate unit in your network.
- Using the Web-Based Manager contains information about how to use the web-based manager, also known as the GUI.
- A Guide to Using the Desktop Models contains information about using FortiGate models 20-90, also known as the Desktop models.
- Basic Administration contains information about basic tasks that should be done to set-up a new FortiGate unit.
- Next Steps contains a list resources that are available to help you with more advanced FortiGate configurations.

Differences between Models

This section examines some of the key types of differences that exist between different FortiGate models.

Features

There are certain features that are not available on all models. For example, the Switch Controller, which allows a FortiGate unit to manage a FortiSwitch unit, is only available on FortiGate models 100D, 140D, 200D, 240D, 600C, 800C, and 1000C.

Other features may be available only through the CLI on models, while other models have options in the web-based manager. For example, SSL content inspection is a CLI-only feature on FortiGate models 20C, 30C, and 40C, while models 60C+ have options in the web-based manager.

For more information about some of the features that vary by model, please see the Feature/Platform Matrix.

If there is a feature you believe your FortiGate model supports that does not appear in the web-based manager as expected, go to **System > Config > Features** and ensure the feature is turned on. For more information, see Feature settings on page 193.

Names

Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called **lan**, while on other units it is called **internal**.

Menus

Menus may vary by model. For example, on some FortiGate units, the main menu option **Router** is not available. Instead, routing is configured by going to **System > Network > Routing.**

Installation

This section provides information about how to install your FortiGate and use it in your network, after you have finished the initial set-up outlined in the FortiGate model's QuickStart Guide. The section also provides troubleshooting methods to use if the FortiGate does not function as desired after completing the installation.

The following topics are included in this section:

NAT/Route Mode vs Transparent Mode
Installing a FortiGate in NAT/Route Mode
Installing a FortiGate in Transparent Mode
Troubleshooting your FortiGate Installation
Using Port Pairing to Simplify Transparent Mode

NAT/Route Mode vs Transparent Mode

A FortiGate unit can operate in one of two modes: NAT/Route or Transparent.

NAT/Route mode is the most common operating mode. In this mode, a FortiGate unit is installed as a gateway or router between two networks. In most cases, it is used between a private network and the Internet. This allows the FortiGate to hide the IP addresses of the private network using network address translation (NAT). NAT/Route mode is also used when two or more Internet service providers (ISPs) will be used to provide the FortiGate with redundant Internet connections.

A FortiGate unit in Transparent mode is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in Transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. Transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

Installing a FortiGate in NAT/Route Mode

There are two main types of FortiGate installations using NAT/Route mode: standard installations that receive Internet access from a single Internet service provider (ISP) and installations that have two or more ISPs for redundant Internet connections. For both installations, the first step is to select which internal Switch mode you require your FortiGate to operate in.

Selecting an Internal Switch mode

The internal Switch mode determines how the FortiGate's physical ports are managed by the FortiGate. The two main modes are Switch mode and Interface mode.

Switch mode vs Interface mode

In Switch mode, all of the internal interfaces are part of the same subnet and treated as a single interface, which is called either **lan** or **internal** by default, depending on the FortiGate model. Switch mode is commonly used in settings where the network layout is fairly basic, with most users being on the same subnet.

In Interface mode, the physical interfaces of the FortiGate unit are configured and handled individually, with each interface having its own IP address. Interfaces can be logically or virtually combined by configuring them as part of either hardware or software switches (for more information, see Hardware Switches vs Software Switches on page 165), which allow multiple interfaces to be treated as a single interface. FortiGate units that are in Interface mode by default start with a hardware switch called either **lan** or **internal,** depending on the FortiGate model. This mode is designed for complex networks where different subnets are used to compartmentalize the network traffic.

The default mode that a FortiGate starts in varies depending on the model. Switch mode has been the most common factory default setting; however, the number of models that have Interface mode as their default setting is increasing.

In order to determine which mode your FortiGate unit is in, go to **System > Network > Interfaces.** Locate the interface called either **lan** or **internal**, which all FortiGate units have be default. If the interface is listed as a physical interface in the **Type** column, then your FortiGate is in Switch mode. If the interface is a hardware switch, then your FortiGate is in Interface mode.

You can also determine what mode your FortiGate is by going to **System > Dashboard > Status** and enter either of the following commands into the **CLI Console**: `config system global show`. In the output that is displayed after you hit the Enter key, find the line that begins with `set internal-switch-mode`. This will tell you which mode your FortiGate is currently in.

If you need to change the mode your FortiGate unit is in, go to **System > Dashboard > Status** and enter either of the following commands into the **CLI Console**:

Before switching modes, you must make sure that none of the physical ports that make up the **lan** or **internal** interface are referenced in the FortiGate configuration.

1. Command to change the FortiGate to Switch mode:

```
config system global
   set internal-switch-mode switch
end
```

2. Command to change the FortiGate to Interface modeHub mode:

```
config system global
   set internal-switch-mode interface
end
```

There is a third mode, called Hub mode, that is available on some FortiGate models. Hub mode is similar to Switch mode, except the network device that it is emulating is a Layer 2 device instead of Layer 3. In Hub mode, he interfaces do not learn the MAC addresses of the devices on the network they are connected to and may also respond quicker to network changes in some circumstances.

You should only select Hub mode if you are having network performance issues when operating with Switch mode. The configuration of the FortiGate unit is the same whether in Switch mode or Hub mode.

Hardware Switches vs Software Switches

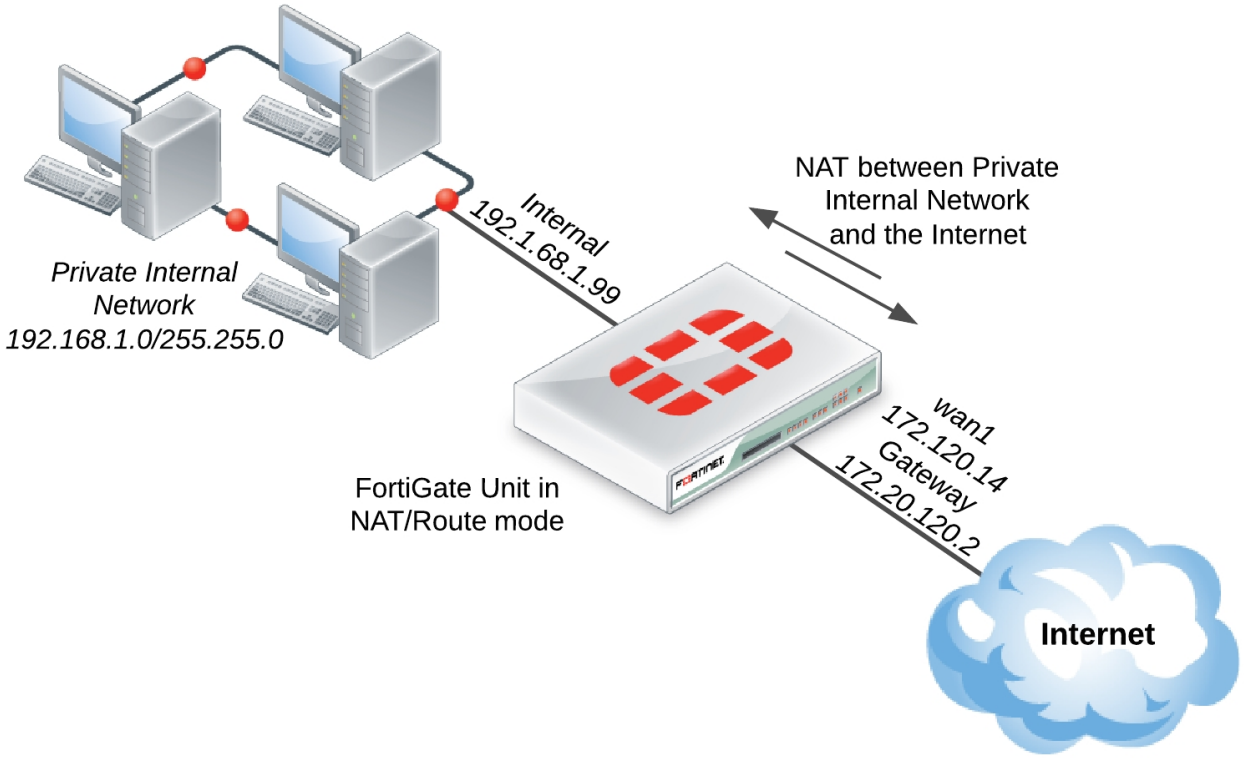
Both hardware and software switches are used to to allow ports to be grouped together and treated as a single interface. The main difference between the two types of switches is that hardware switches use the underlying switch chip/driver to handle all of the switching directly, while software switches do this in the FortiOS software.

The two types of switches also have differences in which commands and features are available, which vary depending on your FortiGate's model. In most situations, using a hardware switch is preferred for better performance, with software switches used in cases where a feature is required that is unavailable for a hardware switch.

For more information about creating hardware and software switches, please refer to the System Administration handbook.

Standard Installation in NAT/Route Mode

Network with a FortiGate unit in NAT/Route mode and a single ISP



1. Connect the FortiGate's Internet-facing interface (typically WAN1) to your ISP-supplied equipment.
2. Connect a PC to the FortiGate using an internal port (typically port 1).
3. Power on the ISP's equipment, the FortiGate unit, and the PC on the internal network.
4. From the PC on the internal network, connect to the FortiGate's web-based manager using either FortiExplorer or an Internet browser (for information about connecting to the web-based manager, please see your models QuickStart Guide). Login using an admin account (the default admin account has the username `admin` and no password).

5. Go to **System > Network > Interfaces** and edit the Internet-facing interface. Set **Addressing Mode** to **Manual** and the **IP/Netmask** to your public IP address. Select **OK**.
6. Edit the internal interface. Set **Addressing Mode** to **Manual** and set the **IP/Netmask** to the private IP address you wish to use for the FortiGate. Select **OK**.
7. Go to **Router > Static > Static Routes** (or **System > Network > Routing**, depending on your FortiGate model) and select **Create New** to add a default route. Set the **Destination IP/Mask** to 0.0.0.0/0.0.0.0, the **Device** to the Internet-facing interface, and the **Gateway** to the gateway (or default route) provided by your ISP or to the next hop router, depending on your network requirements. Select **OK**.

A default route always has a Destination IP/Mask of 0.0.0.0/0.0.0.0. Normally, you would have only one default route. If the static route list already contains a default route, you can either edit it or delete it and add a new one.

8. (Optional) The FortiGate unit's DNS Settings are set to use FortiGuard DNS servers by default, which is sufficient for most networks. However, if you need to change the DNS servers, go to **System > Network > DNS** and add **Primary** and **Secondary** DNS servers. Select **Apply**.
9. If your network uses IPv4 addresses, go to **Policy & Objects > Policy > IPv4** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

Some FortiGate models include the IPv4 security policy in the default configuration. If you have one of these models, this step has already been done for you and as soon as your FortiGate unit is connected and the computers on your internal network are configured, users should be able to access the Internet.

If your network uses IPv6 addresses, go to **Policy & Objects > Policy > IPv6** and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Config > Features**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.

In the policy, set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the Internet-facing interface. You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.

Make sure the **Action** is set to **ACCEPT**. Turn on **NAT** and make sure **Use Destination Interface Address** is selected. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or web filtering, until after you have successfully installed the FortiGate unit. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

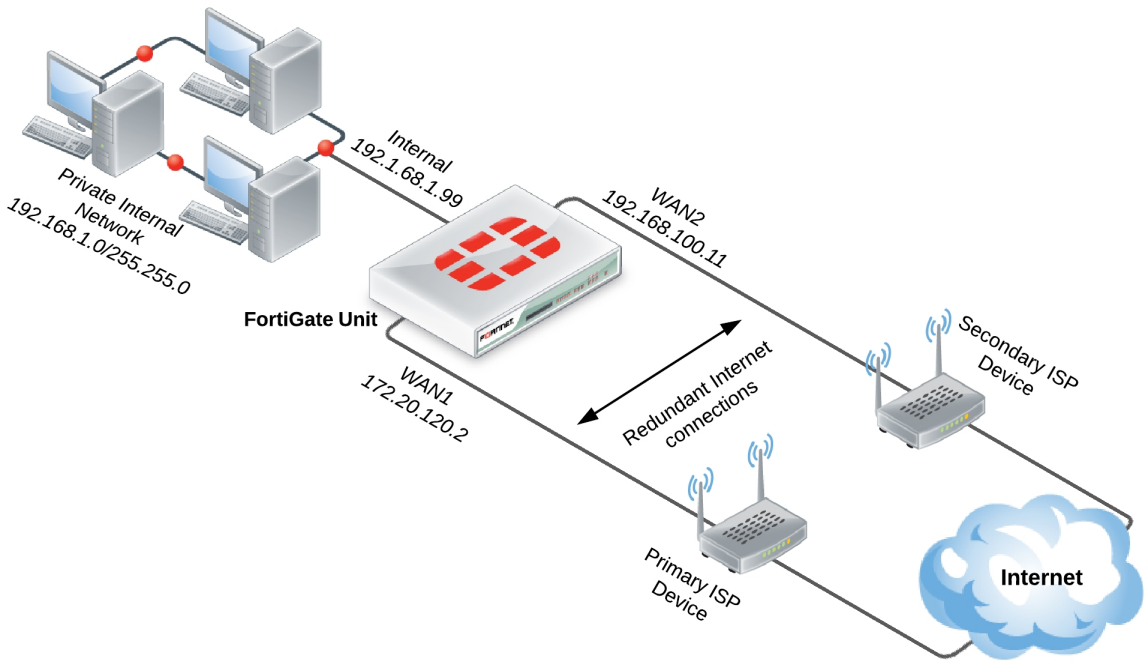
Results

Users on the internal network are now able to browse the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

Redundant Internet Installation in NAT/Route Mode

If you have previously configured your FortiGate using the standard installation, you will have to delete all routes and policies that refer to an interface that will be used to provide redundant Internet. This includes the default Internet access policy that is included on many FortiGate models.

Network with a FortiGate unit in NAT/Route mode using redundant Internet



1. Connect the FortiGate's Internet-facing interfaces (typically WAN1 and WAN2) to your ISP-supplied equipment.
2. Go to **System > Network > WAN Link Load Balancing** to create a WAN link interface, which is used to group multiple Internet connections together so that the FortiGate unit can treat them as a single interface.

If you are using FortiOS 5.2.0, go to **System > Network > Interfaces** and select **Create New > Virtual WAN** to create a virtual WAN link (this feature was renamed WAN link interface in FortiOS 5.2.1).

3. Select an appropriate method of **WAN Load Balancing** from the following options:

- **Source IP based -** The next hop is based on the traffic's source IP address.
- **Weighted Round Robin** - Weight is input for all the active members of the WAN link.
- **Spill-over** - A traffic cap is defined for active members; when it is exceeded, the traffic will automatically activate the standby link.
- **Source-Destination IP based** - The next hop is based on both the traffic's source and destination IP address.
- **Measured-Volume based -** A volume ratio is set for each active member of the WAN link.

4. Add your Internet-facing interfaces to the WAN link interface, configuring load balancing as required for each interface.
5. Go to **Router > Static > Static Routes** and create a new default route. Set **Device** to the virtual WAN link.
6. If your network uses IPv4 addresses, go to **Policy & Objects > Policy > IPv4** and select **Create New** to add a security policy that allows users on the private network to access the Internet.
   If your network uses IPv6 addresses, go to **Policy & Objects > Policy > IPv6** and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Config > Features**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.
   In the policy, set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the WAN link interface. You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.
7. Make sure the **Action** is set to **ACCEPT**. Turn on **NAT** and make sure **Use Destination Interface Address** is selected. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or web filtering, until after you have successfully installed the FortiGate unit. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

Results

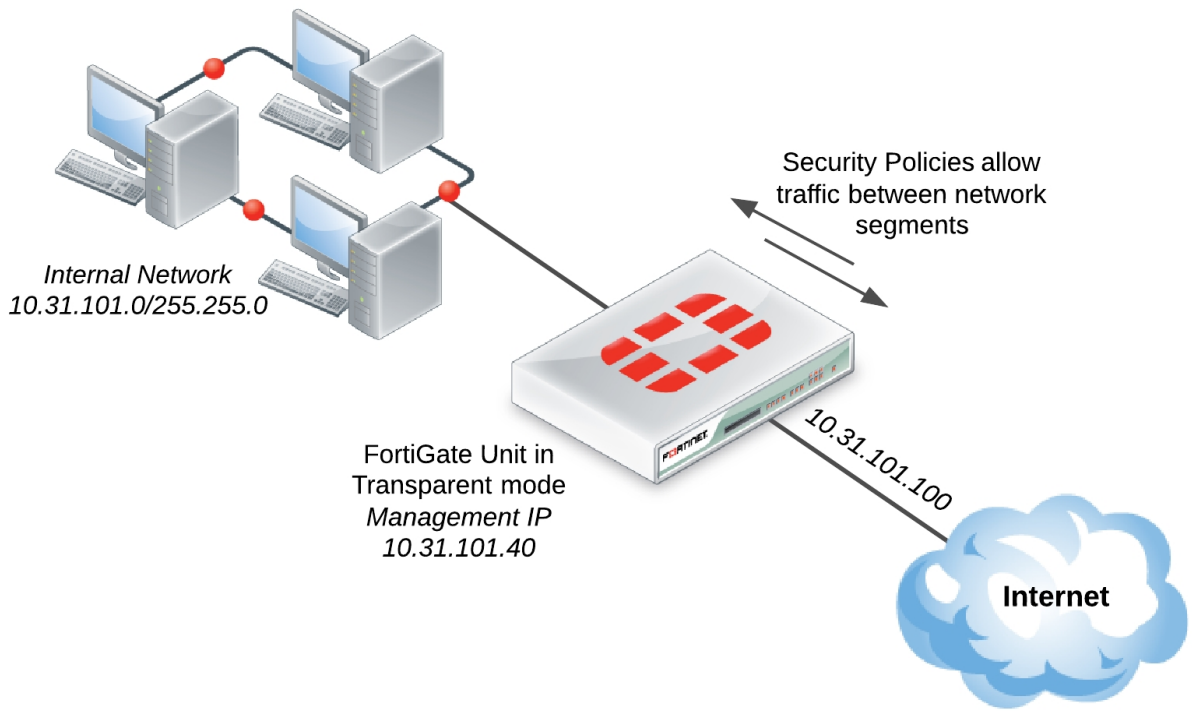
Users on the internal network are now able to browse the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

The amount of traffic will use an individual member of the WAN link interface will depend on the load balancing method you selected. You can view this usage by going to **System > FortiView > All Sessions** and viewing the **Dst Interface** column. If this column is not shown, right-click on the title row and select **Dst Interface** from the dropdown menu. Scroll to the bottom of the menu and select **Apply**.

Installing a FortiGate in Transparent Mode

Changing to Transparent mode removes most configuration changes made in NAT/Route mode. To keep your current NAT/Route mode configuration, backup the configuration using the **System Information** widget, found at **System > Dashboard > Status**.

Network with a FortiGate unit in Transparent mode



1. Before connecting the FortiGate unit to your network, go to **System > Dashboard > Status** and locate the **System Information** widget. Beside **Operation Mode**, select **Change**.
2. Set the **Operation Mode** to **Transparent**. Set the **Management IP/Netmask** and **Default Gateway** to connect the FortiGate unit to the internal network. Select **OK**.
3. Access the web-based manager by browsing to the new management IP.
4. (Optional) The FortiGate unit's DNS Settings are set to use FortiGuard DNS servers by default, which is sufficient for most networks. However, if you need to change the DNS servers, go to **System > Network > DNS** and add **Primary** and **Secondary** DNS servers. Select **Apply**.
5. If your network uses IPv4 addresses, go to **Policy & Objects > Policy > IPv4** and select **Create New** to add a security policy that allows users on the private network to access the Internet.
   If your network uses IPv6 addresses, go to **Policy & Objects > Policy > IPv6** and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Config > Features**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.
   Set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the Internet-facing interface (typically WAN1). You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.
6. Make sure the **Action** is set to **ACCEPT**. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or web filtering, until after you have successfully installed the FortiGate unit. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

7. Go to **System > Dashboard > Status** and locate the **System Resources** widget. Select **Shutdown** to power off the FortiGate unit.
   Alternatively, you can also use the CLI command `execute shutdown`.
8. Connect the FortiGate unit between the internal network and the router.
9. Connect the Internet-facing interface to the router's internal interface and connect the internal network to the FortiGate using an internal port (typically port 1).
10. Power on the FortiGate unit. You will experience downtime before the FortiGate unit starts up completely.

Results

Users on the internal network are now able to browse to the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

If a FortiGate unit operating in Transparent mode is installed between your internet network and a server that is providing a network service to the internal network, such as DNS or DHCP, you must add a wan1-to-internal policy to allow the server's response to flow through the FortiGate unit and reach the internal network.

Troubleshooting your FortiGate Installation

If your FortiGate does not function as desired after completing the installation, try the following troubleshooting methods (those methods that are only applicable to one transparent mode are marked):

1. **Use FortiExplorer if you can't connect to the FortiGate over Ethernet.**
   If you can't connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. See your FortiGate unit's QuickStart Guide for details.
2. **Check for equipment issues.**
   Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network. You will also find detailed information about the FortiGate unit LED indicators.
3. **Check the physical network connections.**
   Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.
   Also, check the **Unit Operation** widget, found at **System > Dashboard > Status**, to make sure the ports used in the connections are shown in green.
4. **Verify that you can connect to the internal IP address of the FortiGate unit (NAT/Route mode).**
   Connect to the web-based manager from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`.
   If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the web-based manager, check the settings for administrative access on that interface.
5. **Verify that you can connect to the management IP address of the FortiGate unit (Transparent mode).**
   From the internal network, attempt to ping the management IP address. If you cannot connect to the internal

interface, verify the IP configuration of the PC and make sure the cables are connected and all switches and other devices on the network are powered on and operating. Go to the next step when you can connect to the internal interface.

6. **Check the FortiGate interface configurations (NAT/Route mode).**
   Check the configuration of the FortiGate interface connected to the internal network, and check the configuration of the FortiGate interface that connects to the Internet to make sure **Addressing Mode** is set to the correct mode.
7. **Verify the security policy configuration.**
   Go to **Policy & Objects > Policy > IPv4** or **Policy & Objects > Policy > IPv6** and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the **Sessions** column to ensure that traffic has been processed (if this column does not appear, right-click on the title row, select **Sessions**, and select **Apply**).
   If you are using NAT/Route mode, check the configuration of the policy to make sure that **NAT** is turned on and that **Use Destination Interface Address** is selected.
8. **Verify that you can connect to the Internet-facing interface's IP address (NAT/Route mode).**
   Ping the IP address of the FortiGate's Internet-facing interface. If you cannot connect to the interface, the FortiGate unit is not allowing sessions from the internal interface to Internet-facing interface.
9. **Verify the static routing configuration (NAT/Route mode).**
   Go to **Router > Static > Static Routes** or **System > Network > Routing** and verify that the default route is correct. View the Routing Monitor (found either on the same page or at **Router > Monitor > Routing Monitor**) and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as **Connected**, one for each connected FortiGate interface.
10. **Verify that you can connect to the gateway provided by your ISP.**
    Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.
11. **Verify that you can communicate from the FortiGate unit to the Internet.**
    Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.
12. **Verify the DNS configurations of the FortiGate unit and the PCs.**
    Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`
    If the name cannot be resolved, the FortiGate unit or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.
13. **Confirm that the FortiGate unit can connect to the FortiGuard network.**
    Once registered, the FortiGate unit obtains antivirus and application control and other updates from the FortiGuard network. Once the FortiGate unit is on your network, you should confirm that it can reach the FortiGuard network.
    First, check the **License Information** widget to make sure that the status of all FortiGuard services matches the services that you have purchased.
    Go to **System > Config > FortiGuard**. Expand **Web Filtering and Email Filtering Options** and select **Test Availability**. After a minute, the web-based manager should indicate a successful connection.
14. **Consider changing the MAC address of your external interface (NAT/Route mode).**
    Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate unit to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
   edit <interface>
      set macaddr <xx:xx:xx:xx:xx:xx>
   end
```

```
end
```

15. Check the FortiGate bridge table (Transparent mode).
When the FortiGate is in Transparent mode, the unit acts like a bridge sending all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate unit.
Each bridge listed is a link between interfaces. Where traffic is flowing between interfaces, you expect to find bridges listed. If you are having connectivity issues, and there are no bridges listed that is a likely cause. Check for the MAC address of the interface or device in question.
To list the existing bridge instances on the FortiGate unit, use the following CLI command:

```
diagnose netlink brctl name host root.b
show bridge control interface root.b host.
fdb: size=2048, used=25, num=25, depth=1
Bridge root.b host table
port no device devname mac addr ttl attributes
3 4 wan1 00:09:0f:cb:c2:77 88
3 4 wan1 00:26:2d:24:b7:d3 0
3 4 wan1 00:13:72:38:72:21 98
4 3 internal 00:1a:a0:2f:bc:c6 6
1 6 dmz 00:09:0f:dc:90:69 0 Local Static
3 4 wan1 c4:2c:03:0d:3a:38 81
3 4 wan1 00:09:0f:15:05:46 89
3 4 wan1 c4:2c:03:1d:1b:10 0
2 5 wan2 00:09:0f:dc:90:68 0 Local Static
```

If your device's MAC address is not listed, the FortiGate unit cannot find the device on the network. This could indicate that the device is either not connected or not operating. Check the device's network connections and make sure they are connected and operational.

16. Either reset the FortiGate unit to factory defaults or contact the technical assistance center.
If all else fails, reset the FortiGate unit to factory defaults using the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.

Resetting the FortiGate unit to factory defaults puts the unit back into NAT/Route mode.

You can also contact the technical assistance center. For contact information, go to support.fortinet.com.

Using Port Pairing to Simplify Transparent Mode

Once you have successfully installed a FortiGate in Transparent mode, you can use port pairing to simplify the configuration.

When you create a port pair, all traffic accepted by one of the paired interfaces can only exit out the other interface. Restricting traffic in this way simplifies your FortiGate configuration because security policies between these interfaces are pre-configured.

Traffic between port-paired interfaces does not check the bridge table and MAC addresses are not learned. Instead traffic received by one interface in a port pair is forwarded out the other (if allowed by a firewall policy). This makes port pairing useful for unusual topologies where MAC addresses do not behave normally. For example, port paring can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

1. Go to *System* > *Network* > *Interfaces*. Select *Create New* > *Port Pair*. Create a port pair that includes both interfaces.
2. Go to *Policy & Objects* > *Policy* > *IPv4*. Create two security policy that allow traffic to flow between the interfaces in the port pair (for example, if you are pairing *wan1* and *Internal*, create a wan1-to-Internal policy and an Internal-to-wan1 policy).

Traffic should now be able to flow between the interfaces in the port pair. You can verify this by going to *Log & Report* > *Traffic Log* > *Forward Traffic*.

Using the Web-Based Manager

This section contains an introduction to the web-based manager administrative interface (sometimes referred to as a graphical user interface, or GUI) of your FortiGate unit and the information you can access from the various dashboards and tables.

The following topics are included in this section:

Connecting to the web-based manager
Menus
Dashboards
Feature settings
Information tables
Text strings

Connecting to the web-based manager

After you have completed the initial installation for your FortiGate unit, there are two ways to connect to the web-based manager: using FortiExplorer or a web browser.

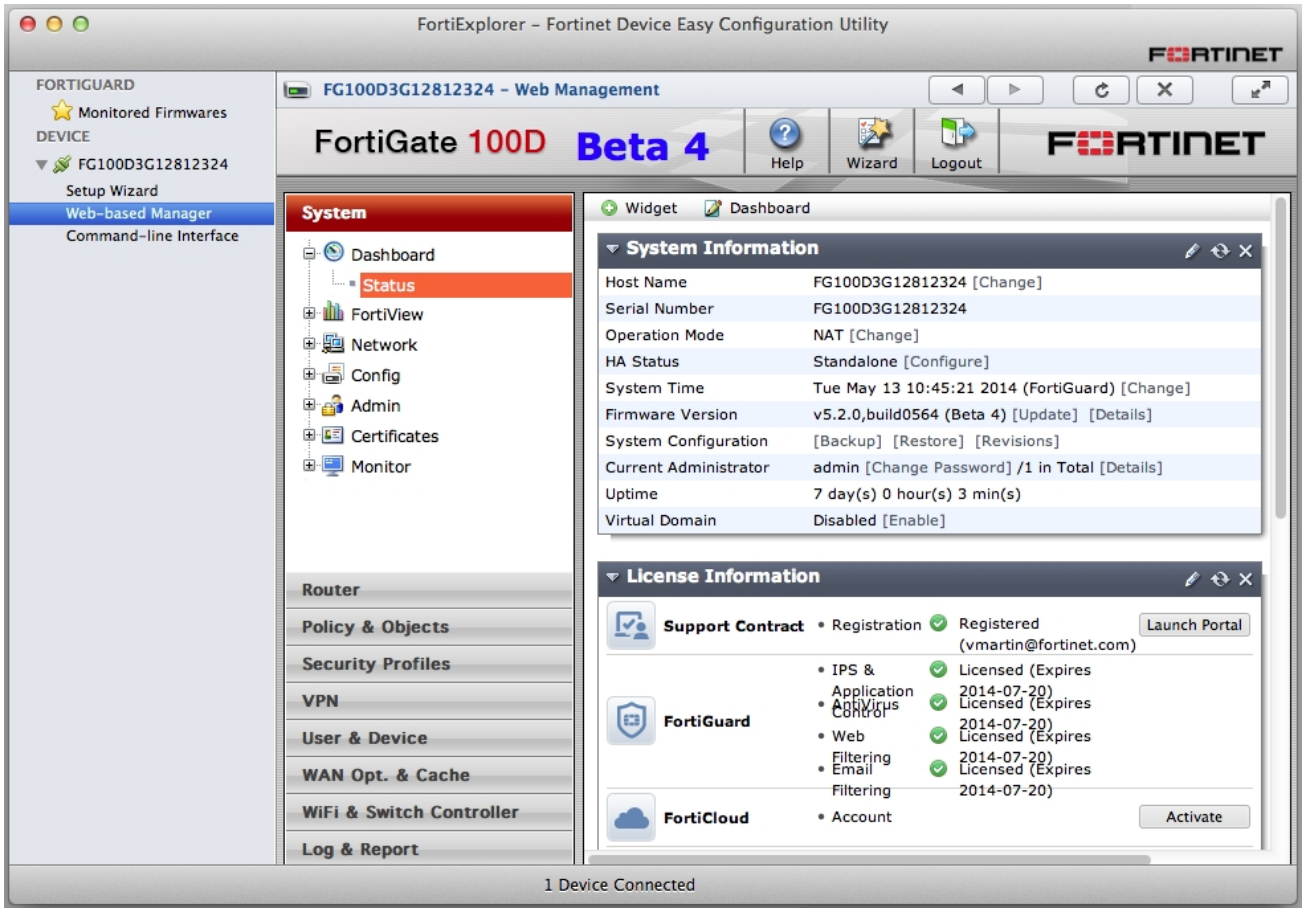
FortiExplorer

To connect to the web-based manager using FortiExplorer, connect your management computer to your FortiGate unit's USB MGMT port, using the cable that came with the unit. FortiExplorer should open automatically once the devices are connected; if it does not, open the program manually.

To connect to the web-based manager, go to **Devices > Web-based Manager** and enter your username and password. If you have not changed the admin account's password, use the default username, `admin`, and leave the password field blank.

The web-based manager will now be displayed in FortiExplorer.

Connecting to the web-based manager with FortiExplorer



Web browser

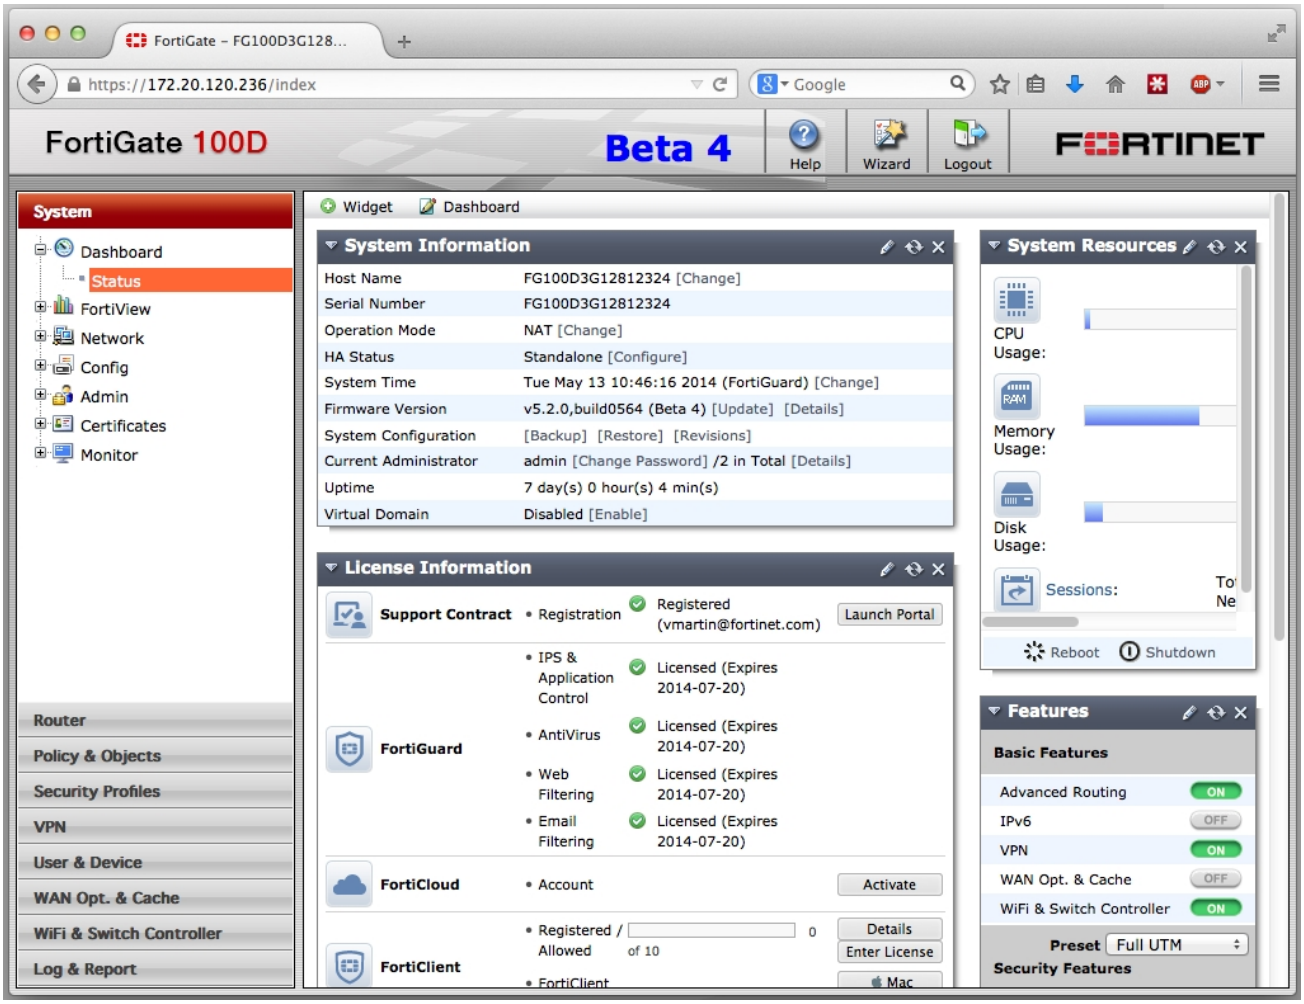
The recommended minimum screen resolution for properly displaying the web-based manager is 1280 by 1024. Check the FortiOS Release Notes for information about browser compatibility.

In order to connect to the web-based manager using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access, with the IP address 192.168.1.99.

Browse to https://192.168.1.99 and enter your username and password. If you have not changed the admin account's password, use the default username, `admin`, and leave the password field blank.

The web-based manager will now be displayed in your browser.

Connecting to the web-based manager with a web browser (Firefox)



If you wish to use a different interface to access the web-based manager, do the following:

1. Go to **System > Network > Interfaces** and edit the interface you wish to use for access. Take note of its assigned IP address.
2. Beside **Administrative Access**, select **HTTPS**. You can also select **HTTP**, although this is not recommended as the connection will be less secure.
3. Select **OK**.
4. Browse to the IP address using your chosen protocol.

The web-based manager will now be displayed in your browser.

Menus

Some menus may not initially appear on your FortiGate, while others only appear on certain FortiGate models or when certain features/modes are enabled. If there is a menu you believe your FortiGate model supports that does not appear in the web-based manager as expected, go to **System > Config > Features** and ensure the feature is turned on. For more information, see Feature settings on page 193.

The web-based manager contains the following main menus, which provide access to configuration options for most of the FortiOS features:

System	Configure system settings, such as network interfaces, virtual domains (VDOMs), DNS services, administrators, certificates, High Availability (HA), system time, set system options, and set display options on the web-based manager. The **System** menu also contains the Status and FortiView dashboards. For more information, see Dashboards on page 178 .
Router	Configure static, dynamic and multicast routing and view the router monitor. On certain FortiGate models, routing is configured by going to **System > Network > Routing**.
Policy & Objects	Configure firewall policies, protocol options, the Central NAT Table, and supporting content for policies including scheduling, services, traffic shapers, addresses, virtual IP and load balancing.
Security Profiles	Configure antivirus and email filtering, web filtering, intrusion protection, data leak prevention, application control, VOIP, ICAP and Client Reputation.
VPN	Configure IPsec and SSL virtual private networking.
User & Device	Configure user accounts and user authentication including external authentication servers.This menu also includes endpoint security features, such as FortiClient configuration and application detection patterns.
WAN Opt. & Cache	Configure WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers.
WiFi Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu is called **WiFi & Switch Controller** and has additional features allowing for FortiSwitch units to be managed by the FortiGate.
Log & Report	Configure logging and alert email as well as reports. View log messages and reports.
Current VDOM	This menu only appears when VDOMs are enabled on the unit and is used to switch between VDOMs.

Dashboards

The various dashboard menus provides a way to access information about network activity and events, as well as configure basic system settings.

There are two main dashboards: the Status Dashboard and the FortiView Dashboards.

Status Dashboard

The **Status Dashboard** can be found by going to **System > Dashboard > Status**. The dashboard consists of a number of widgets, each displaying a different set of information. A number of pre-configured widgets are available which can be customized to meet your needs.

To choose which widgets will be shown, select **Widget** and select the widget you wish to view, which will add it to the dashboard. Widgets can be rearranged in the **Status Dashboard** for easier access and viewing. You can also change the display from two columns to one by selecting the **Dashboard** button, selecting **Edit Dashboard** and choosing the one column display from the options.

Custom Dashboards

You can create custom dashboards that will be added to the menu under the default **Status Dashboard**. You can add, remove, or rename a dashboard, regardless of whether it is default. You can also reset the Dashboard menu to its default settings by selecting **Reset Dashboards**.

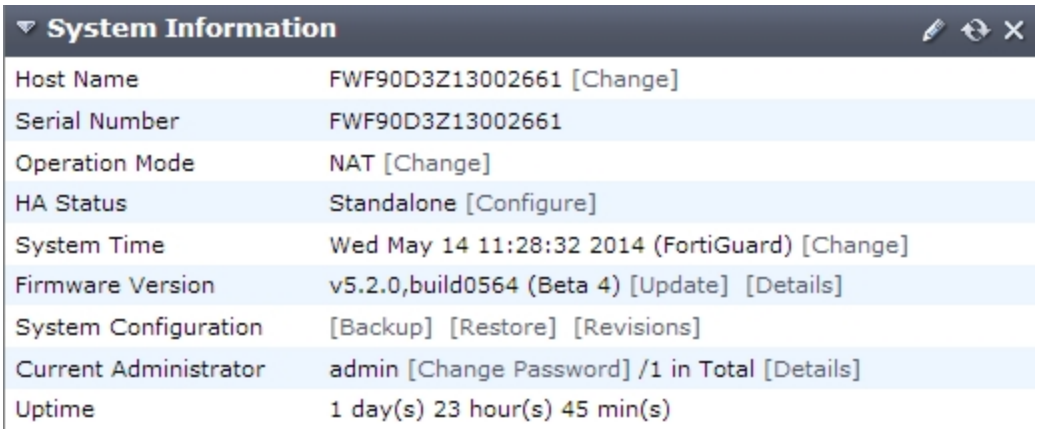
If VDOMs are enabled, only the dashboards within Global are available for configuration.

To add a dashboard

1. Go to **System > Dashboard > Status**.
2. Select **Dashboard**, located at the top left of the page.
3. Select **Add Dashboard**.

System Information

The System Information widget



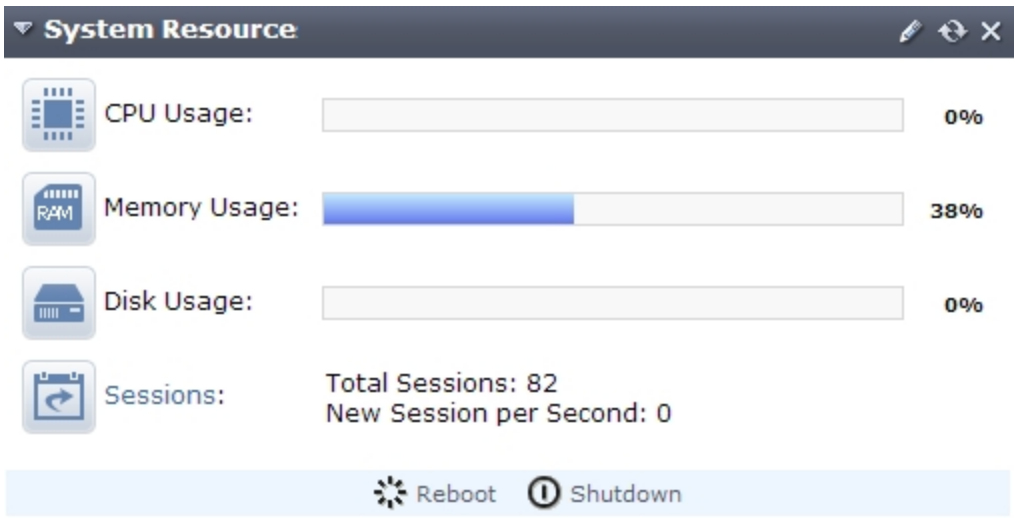
The **System Information** widget shows status information on the FortiGate unit. Some configuration details/modes can be changed through the widget.

Host Name	The name of the FortiGate unit. If the FortiGate unit is in HA mode, this information is not displayed.
Serial Number	The serial number of the FortiGate unit. The serial number is specific to that FortiGate unit and does not change with firmware upgrades.
Operation Mode	The current operating mode of the FortiGate unit (a FortiGate unit can operate in NAT mode or Transparent mode). If virtual domains are enabled, this field shows the operating mode of the current virtual domain. The Global System Status dashboard does not include this information.
HA Status	The status of High Availability (HA) within the cluster. Standalone indicates the FortiGate unit is not operating in HA mode. Active-Passive or Active-Active indicate the FortiGate unit is operating in HA mode. Select **Configure**, to change the HA configuration.
Cluster Name	The name of the HA cluster for this FortiGate unit. The FortiGate unit must be operating in HA mode to display this field.
Cluster Members	The FortiGate units in the HA cluster. Information displayed about each member includes host name, serial number, and whether the FortiGate unit is a primary (master) or subordinate (slave) FortiGate unit in the cluster. The FortiGate unit must be operating in HA mode with virtual domains disabled to display this information.
Virtual Cluster 1 **Virtual Cluster 2**	The role of each FortiGate unit in virtual cluster 1 and virtual cluster 2. The FortiGate unit must be operating in HA mode with virtual domains enabled to display this information.
System Time	The current date and time.
Firmware Version	The version of the current firmware installed on the FortiGate unit.
System Configuration	The time period of when the configuration file was backed up.
Current Administrator	The number of administrators currently logged into the FortiGate unit. Select **Details** to view more information about each administrator that is currently logged in
Uptime	The time in days, hours, and minutes since the FortiGate unit was started or rebooted.
Virtual Domain	Status of virtual domains on your FortiGate unit. This information will only appear when VDOMs have been enabled.

Explicit Proxy	The status of each feature. Select **Enable** or **Disable** to change the status of the feature. When enabled, the menu option appears.
Load Balance	This information will only appear when redundant Internet connections are enabled.

System Resources

The System Resources widget



The **System Resources** widget displays basic FortiGate unit resource usage. This widget displays the information for CPU and memory in either real-time or historical data. For FortiGate units with multiple CPUs, you can view the CPU usage as an average of all CPUs or each one individually.

This widget also is where you reboot or shutdown the FortiGate unit.

The options to reboot or shutdown the FortiGate unit are not available for an admin using the *prof_admin* profile.

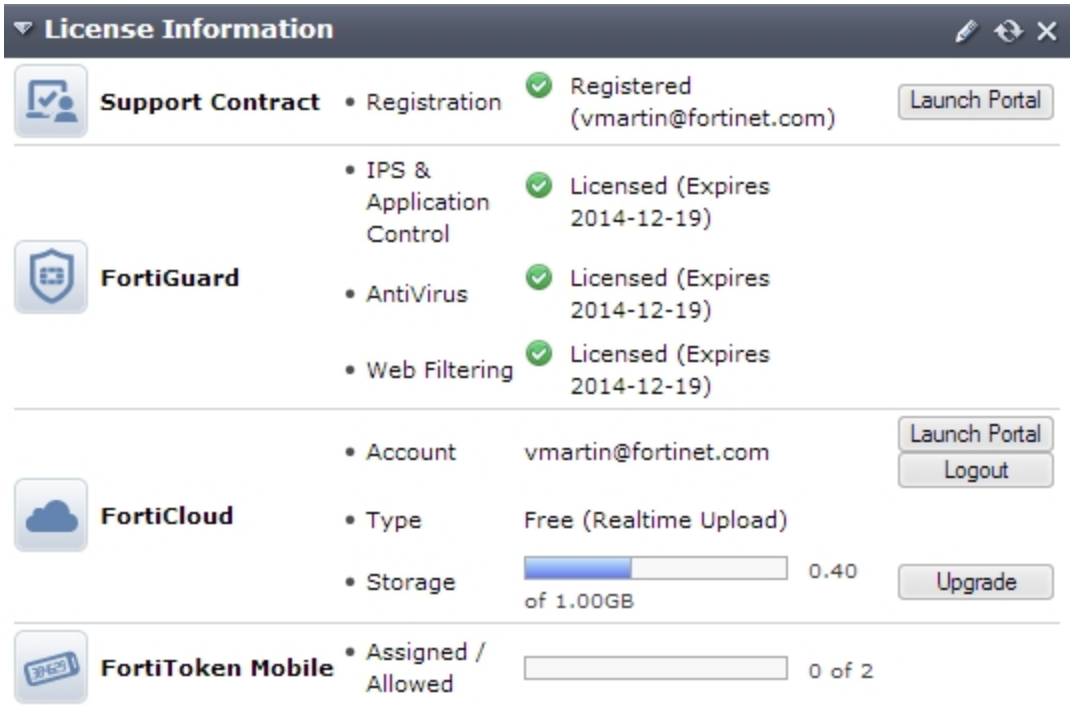
USB Modem

The USB modem widget

The USB modem widget enables you to monitor the status of your USB modem and configure it as needed.

License Information

The License Information widget



The **License Information** widget displays the status of your technical support contract, FortiGuard subscriptions, FortiCloud account, and other licenses.

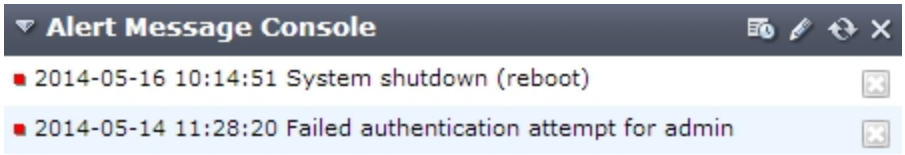
When a new FortiGate unit is powered on, it automatically searches for FortiGuard services. If the FortiGate unit is configured for central management, it will look for FortiGuard services on the configured FortiManager system. The FortiGate unit sends its serial number to the FortiGuard service provider, which then determines whether the FortiGate unit is registered and has valid contracts for FortiGuard subscriptions and FortiCare support services. If the FortiGate unit is registered and has a valid contract, the **License Information** is updated.

When a license is near to its expiry date, an option to extend it will appear that allows you to add a new license as soon as you buy it.

Support Contract	Displays details about your current Fortinet Support contract. If **Not Registered** appears, select **Register** to register the FortiGate unit. If **Expired** appears, select **Renew** for information on renewing your technical support contract. Contact your local reseller. If **Registered** appears, the name of the support that registered this FortiGate unit is also displayed. The various types of contracts that you currently have and the expiry date for each type. You can select **Launch Portal** to log into the Fortinet Support account that registered this FortiGate unit.
FortiGuard Services	Displays your current licenses for services from FortiGuard. Select **Extend** or **Renew** to update any of the licenses (these options only appear when a license is expired or close to expiry).
FortiCloud	Displays details about your current FortiCloud subscription. If the green **Activate** button appears, select it to either create a new account or add the FortiGate unit to an existing account. If you have already activated FortiCloud, the name of the **Account** will be listed. Select **Launch Portal** to view your FortiCloud account in a web browser. Information on the current **Type** and **Storage** is also listed. You can select **Upgrade** to change the type of your FortiCloud account.
FortiClient Software	Displays FortiClient license details and the number of **Register** and **Allowed** FortiClient users. You can select **Details** for more information about the current FortiClient users. This information will only appear when you have a FortiClient license.
FortiToken Mobile	Displays the number of **Assigned** and **Allowed** FortiTokens.
SMS	Displays the number of **Sent** and **Allowed** SMS messages. You can select **Add Messages** to configure a new SMS message. This information will only appear when SMS has been configured.
Virtual Domain	Displays the maximum number of virtual domains the FortiGate unit supports with the current license. For some FortiGate models, you can select the **Purchase More** link to purchase a license key through Fortinet technical support to increase the maximum number of VDOMs.

Alert Message Console

The Alert Messages Console widget



The **Alert Messages Console** widget helps you monitor system events on your FortiGate unit such as firmware changes, network security events, or virus detection events. Each message shows the date and time that the event occurred.

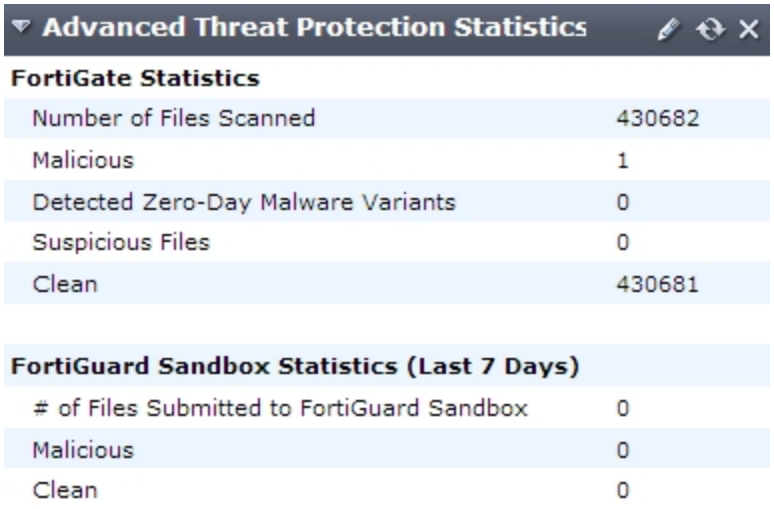
You can configure the alert message console settings to control what types of messages are displayed on the console.

To configure the Alert Message Console

1. Locate the **Alert Message Console** widget within the Dashboard menu.
2. Select the **Edit** icon in the **Alert Message Console** title bar.
3. Select the types of alerts that you do not want to be displayed in the widget.
4. Select **OK**.

Advanced Threat Protection Statistics

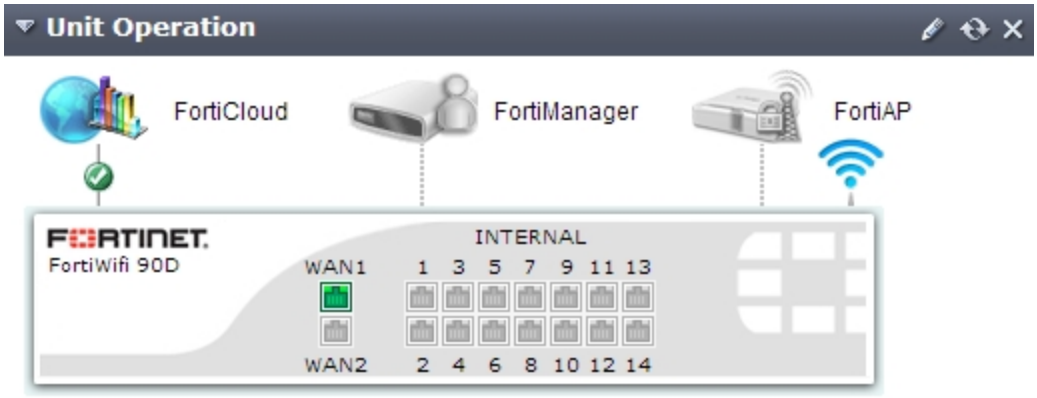
The Advanced Threat Protection Statistics widget



The **Advanced Threat Protection Statistics** widget displays a count of detected malware and files scanned for these types of intrusions. It also displays statics on the number of files sent to FortiGuard Sandbox and the results from sandboxing.

Unit Operation

The Unit Operation widget

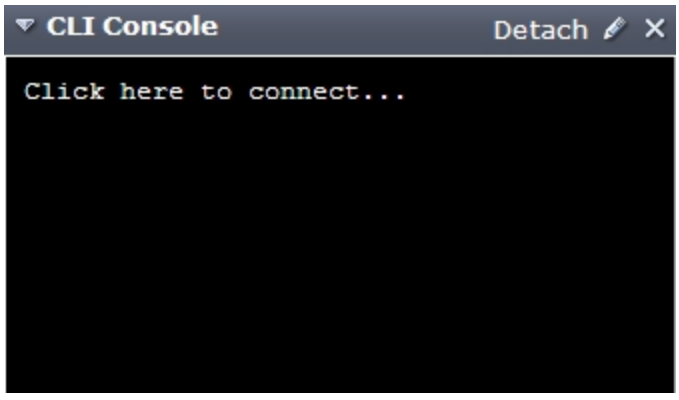


The **Unit Operation** widget is an illustrated version of the FortiGate unit's front panel that shows the status of the FortiGate unit's network interfaces. Interfaces appears green when connected. Hover the mouse pointer over an interface to view further details.

Icons around the front panel indicate when the FortiGate unit is connected to a FortiAnalyzer or FortiManager device, or FortiClient installations. Select the icon in the widget to jump to the configuration page for each device. When connected to one of these devices, a green check mark icon appears next to the icon. If the device communication is configured but the device is unreachable, a red X appears.

CLI Console

The CLI Console widget



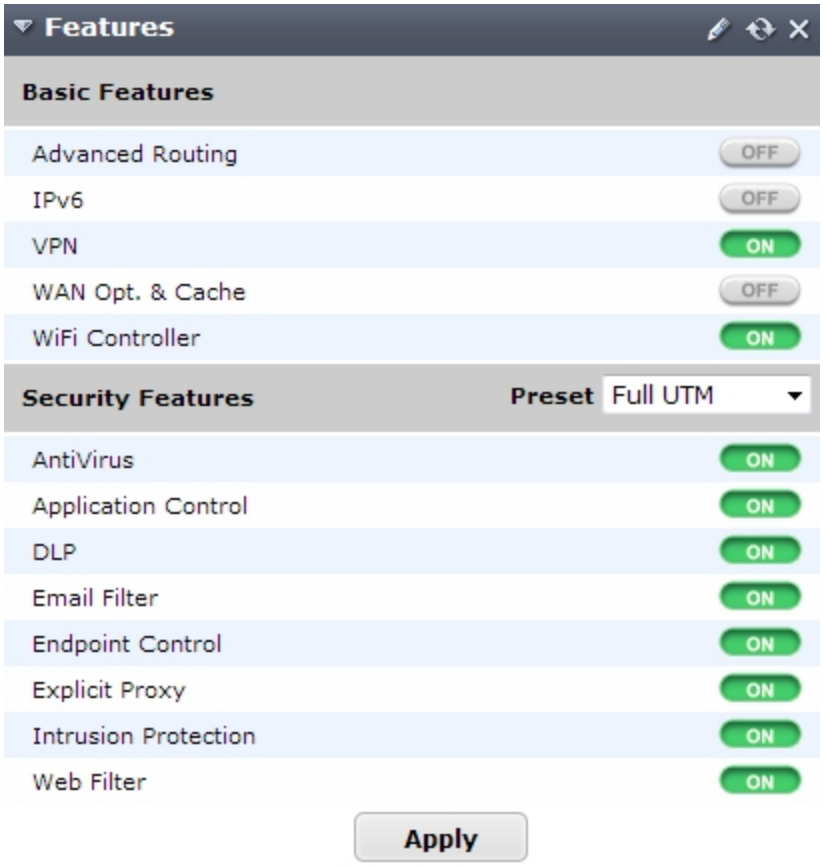
The **CLI Console** widget enables you to access the CLI without exiting from the web-based manager.

The two controls located on the CLI Console widget title bar are **Customize**, and **Detach**.

- **Detach** moves the CLI Console widget into a pop-up window that you can resize and reposition. Select **Attach**. to move the widget back to the dashboard's page.
- **Customize** enables you to change the appearance of the console by selecting fonts and colors for the text and background.

Features

The Features widget



The **Features** widget displays a number of **Basic Features** and **Security Features** and whether or not each feature is currently enabled or disabled. Options for features that are disabled will not appear in the web-based manager.

For more information, see Feature settings on page 193.

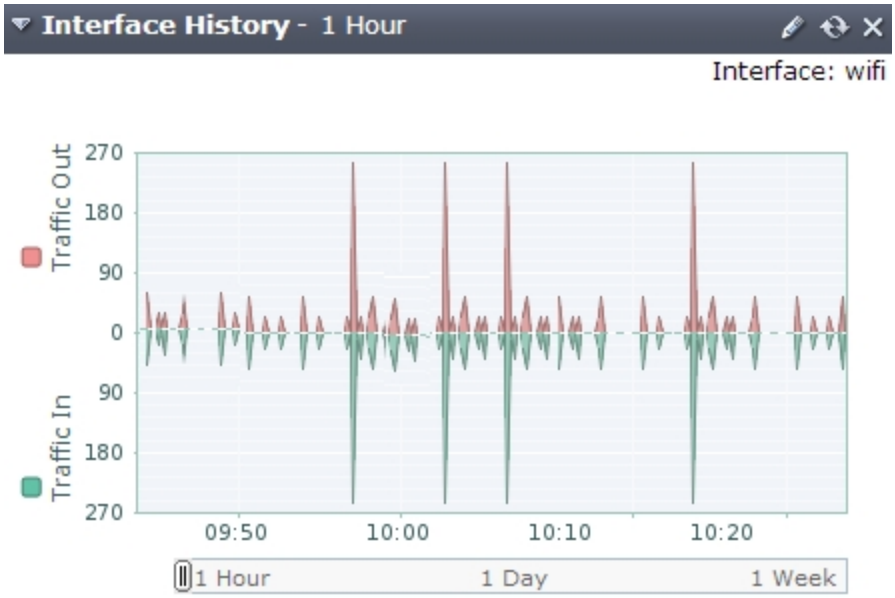
RAID monitor widget

The **RAID Monitor** widget displays the current state of the RAID array and each RAID disk. This widget does not display unless the FortiGate unit has more than one disk installed and is not available for FortiOS Carrier.

Array status icon	Displays the status of the RAID array. • Green with a check mark shows a healthy RAID array. • Yellow triangle shows the array is in a degraded state but it is still functioning. A degraded array is slower than a healthy array. Rebuild the array to fix the degraded state. • A wrench shows the array is being rebuilt. Positioning the mouse over the array status icon displays a text message of the status of the array.
Disk status icon	There is one icon for each disk in the array. • Green with a check mark shows a healthy disk. • Red with an X shows the disk has failed and needs attention. Positioning the mouse over the disk status icon displays the status of the disk, and the storage capacity of the disk.
RAID Level	The RAID level of this RAID array. The RAID level is set as part of configuring the RAID array.
Status bar	The bar shows the percentage of the RAID array that is currently in use.
Used/Free/Total	Displays the amount of RAID array storage that is being used, the amount of storage that is free, and the total storage in the RAID array. The values are in gigabytes.

Interface History

The Interface History widget

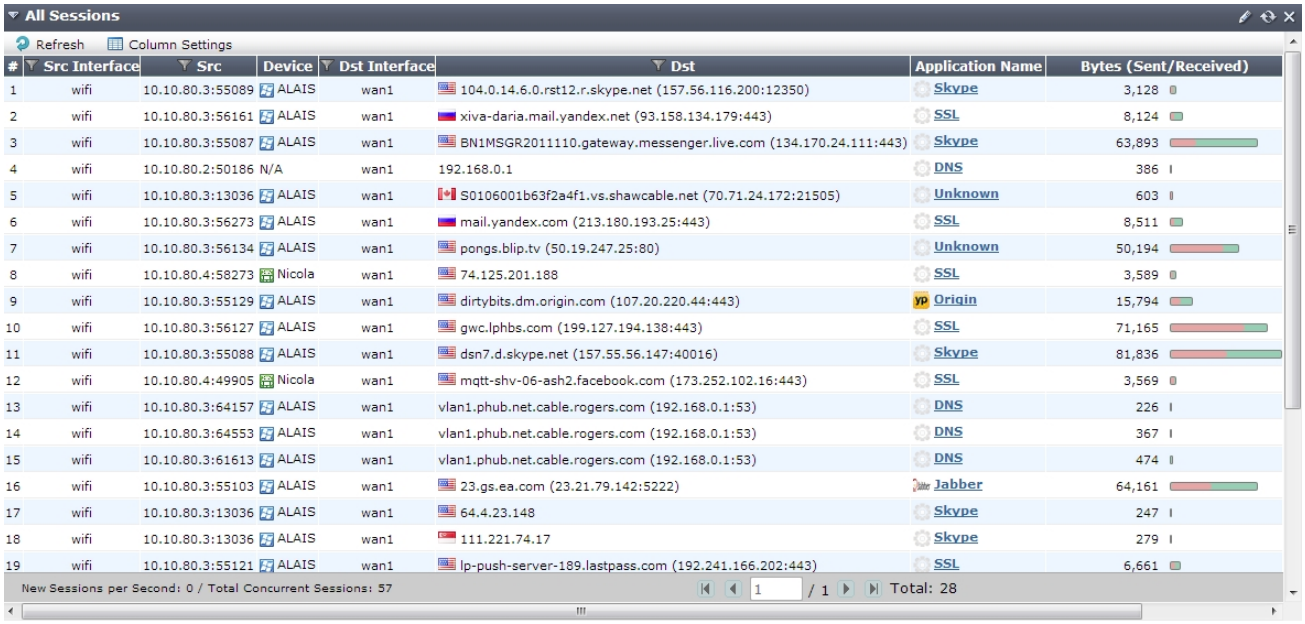


The **Interface History** widget displays the current activity and activity history of a system interface.

The current interface is visible in the top right-hand corner of the widget. You can change the interface that is shown by selecting the **Edit** icon and set **Select Network Interface** to the interface of your choice.

All Sessions

The All Sessions widget



The **All Sessions** widget shows information on your FortiGate's traffic. This widget can only be viewed on a dashboard that is set to have a one column display.

FortiView Dashboards

In order for information to appear in the **FortiView** dashboards, disk logging must be selected for the FortiGate unit. To select disk logging, go to **Log & Report > Log Config > Log Settings**.

Disk logging is disabled by default for some FortiGate units. To enable disk logging, enter the following command in the CLI:

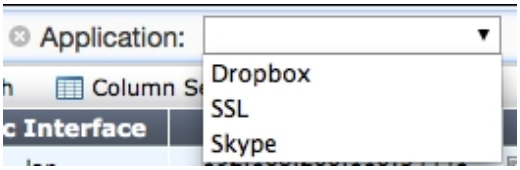
```
config log disk setting
     set status enable
end
```

Please note that flash-based logging has been disabled in FortiOS 5.2 for certain models. To view a complete list of affected models, please refer to the Release Notes.

The **FortiView** dashboards integrate real time and historical dashboards into a single view. These dashboards can be found by going to **Status > FortiView**. Each dashboard will initially display the top 100 sessions but when the results are filtered, other sessions may be displayed.

Each dashboards can be filtered by a variety of attributes. Attributes can be selected by using the dropdown menu located at the top of each widgets that displays only the options that have results; for example, if the only applications used in the are Dropbox, SSL, and Skype, the only options in the dropdown menu for the Application filter will be Dropbox, SSL, and Skype.

Filtering for Applications



Results can also be filtered using the various columns, although not all columns support this.

The dashboards also include different time options, allowing you to see current traffic in real-time, or historical traffic that occurred in the last 5 minutes, 1 hour, or 24 hours.

Historical traffic is only supported on FortiGate models that have local storage. The 24 hours option is also unavailable for desktop models (FortiGate-90 series and below).

Sources

The **Sources** dashboard shows information about the sources of traffic on your FortiGate unit, including user and device. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by source IP, source device, source interface, destination interface, and policy ID.

The Sources dashboard

Source	Device	Sessions	Bytes (Sent/Received)
10.10.80.3	Alais	122	539.94 K
10.10.80.4	Nicola	4	163.12 K
10.10.80.2	Wii	1	386

Applications

The **Applications** dashboard shows information about the applications being used on your network, including application name, category, and risk level. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by application, source interface, destination interface, and policy ID.

In order for information to appear in the **Applications** dashboard, application control must be enabled in a policy.

The Applications dashboard

Application	Category	Risk	Sessions	Bytes (Sent/Received)
DNS	Network.Service		35	9.44 K
Skype	P2P		23	589.99 K
Hola.Unblocker	Proxy		21	440.08 K
SMTPS	Email		1	10.46 K
Dropbox	Storage.Backup		1	12.11 K

Cloud Applications

The **Cloud Applications** dashboard shows information about the cloud applications being used on your network, including application name, category, risk level, login IDs, and, if applicable, the number of videos played. If the cursor is held over the column showing the number of videos, the titles of these videos will be shown. Additional columns show information about sessions and bytes sent or received.

Two different views are available for the Cloud Applications dashboard: applications and users. Applications shows a list of the programs being used. Users shows information on the individual users of the cloud applications, including the username if the FortiGate was able to view the login event.

This dashboard can be filtered by application, source interface, destination interface, and policy ID.

In order for information to appear in the **Cloud Applications** dashboard, an application control profile that has **Deep Inspection of Cloud Applications** turned on must be enabled in a policy and SSL Inspection must use `deep-inspection`.

Destinations

The **Destinations** dashboard shows information about the destination IPs of traffic on your FortiGate unit, as well as the application used. Additional columns show information about sessions and bytes sent or received.

This dashboard can be filtered by destination IP, user, source interface, destination interface, and policy ID.

The Destinations dashboard

Destination	Applicati...	Sessions	Bytes (Sent/Received)
pongs.blip.tv (54.243.171.49)	Unknown	2	71.42 K
gwb.lphbs.com (199.127.194.181)	Unknown	1	45.33 K
notify3.dropbox.com (108.160.167.157)	Dropbox	1	555
dsn0.d.skype.net (157.55.130.156)	Unknown	1	8.29 K
dsn15.d.skype.net (157.55.56.154)	Unknown	1	3.84 K
104.0.14.6.0.rst6.r.skype.net (157.55.133.145)	Unknown	1	5.03 K

Web Sites

The **Web Sites** dashboard lists the top allowed and top blocked web sites. You can view information by domain or by FortiGuard categories by using the options in the top right corner. Each FortiGuard category can be clicked on in order to see a description of the category and several example sites, with content loaded from FortiGuard

on demand. New icons have also been added for FortiGuard category groups. Additional information is provided about domain, browsing time, threat weight, sources, and bytes sent or received.

This dashboard can be filtered by source interface, domain, destination interface, and policy ID.

In order for information to appear in the **Web Sites dashboard**, web filtering must be enabled in a policy, with FortiGuard Categories enabled.

The Web Sites dashboard

Threats

The **Threats** dashboard lists the top users involved in incidents, as well as information on the top threats to your network. Additional information is provided about the threat, category, threat level, threat weight, and number of incidents.

This dashboard can be filtered by source interface, threat type, threat, destination interface, and policy ID.

In order for information to appear in the **Threats** dashboard, **Threat Weight Tracking** must be used.

The Threats dashboard

Threat	Category	Threat Le...	Threat Weight	Incidents
Failed Connection Attempts	Failed Connection Attempts	Medium	30	3

All Sessions

The **All Sessions** dashboard shows information about all FortiGate traffic. To choose which columns you wish to view, select **Column Settings** and place your desired columns in the right-hand box, in the order that you wish them to appear.

This dashboard can be filtered by source IP, destination IP, application, source device, source interface, destination interface, and policy ID. If you have set a filter in a different dashboard before viewing the **All Sessions** dashboard, that filter will remain until manually cleared.

The All Sessions dashboard

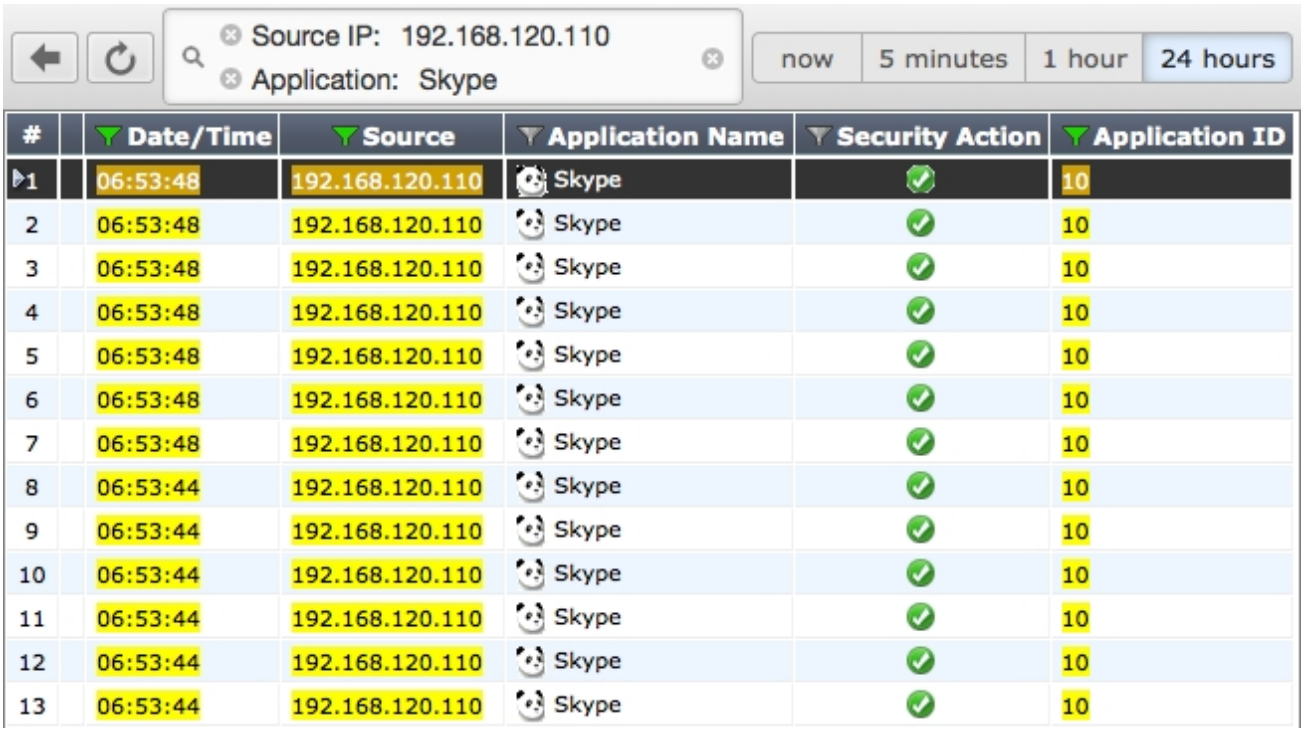
Date/Time	Source	Destination	Application Name	Security Acti...	Threat	Sent / Received
10:49:24	192.168.120.110	188.40.238.250 (analytics.eicar.org)	Unknown			4.11 KB / 11.33 KB
10:49:15	192.168.120.110	188.40.238.250 (analytics.eicar.org)	Unknown		AV EICAR_TEST_FILE	10.65 KB / 237.91 KB
10:44:33	192.168.120.110	38.127.167.7 (lastpass.com)	LastPass			2.02 KB / 8.98 KB
10:44:33	192.168.120.110	108.160.167.148 (d.dropbox.com)	Dropbox_Client.Sync			4.14 KB / 6.59 KB
10:44:26	192.168.120.110	134.170.24.141 (gateway.messenger.live.com)	Skype			10.75 KB / 33.54 KB
10:44:05	192.168.120.110	63.245.217.208 (phx-sync-13-2-8.services.mozilla.com)	SSL			8.66 KB / 4.39 KB

Drilldown Options

In all FortiView dashboards except for the **All Sessions** dashboard, you can view more information about a particular session by right-clicking or double-clicking on the session to display the **Drilldown to details...** option, which opens a summary page that includes further information about applications, sources, destinations, and sessions where applicable.

From this summary page, you can access automatically filtered logs that will show a list of applicable sessions. For example, if you have picked the IP address 192.168.120.110 from the **Sources** dashboard, you can then select **Drilldown to details...** for Skype from the **Applications** column. This will open a log that displays all sessions from 192.168.1.1 that used Skype. From this page, you can select **Drilldown to details...** for any individual session, in order to view the log entry for that session.

Viewing Skype sessions from the Source Address 192.168.120.110



#	Date/Time	Source	Application Name	Security Action	Application ID
1	06:53:48	192.168.120.110	Skype	✓	10
2	06:53:48	192.168.120.110	Skype	✓	10
3	06:53:48	192.168.120.110	Skype	✓	10
4	06:53:48	192.168.120.110	Skype	✓	10
5	06:53:48	192.168.120.110	Skype	✓	10
6	06:53:48	192.168.120.110	Skype	✓	10
7	06:53:48	192.168.120.110	Skype	✓	10
8	06:53:44	192.168.120.110	Skype	✓	10
9	06:53:44	192.168.120.110	Skype	✓	10
10	06:53:44	192.168.120.110	Skype	✓	10
11	06:53:44	192.168.120.110	Skype	✓	10
12	06:53:44	192.168.120.110	Skype	✓	10
13	06:53:44	192.168.120.110	Skype	✓	10

In the **All Sessions** dashboard, filters are also used to narrow down what results are shown. If you are viewing historical traffic in the **All Sessions** dashboard, you can also add an element to a filter by right-clicking the element and selecting **Set Filter**.

Feature settings

Feature settings are used to disable features which are not required for network administration. Disabling features also removes all related configuration options from the web-based manager.

Some features are disabled by default and must be enabled in order to configure them using the web-based manager.

Enabling/disabling features

Feature Settings can be selected using the **Features** widget on the Status page, found at **System > Dashboard > Status**. When viewed in the Status Dashboard, the **Features** widget only displays a limited number of features. To view the entire list, select the **Edit** option for the widget.

Feature Settings can also be found at **System > Config > Features**, where additional features are also available by selecting **Show More**.

Once you have accessed Feature Settings, ensure all features you wish to use are turned on, while features you wish to hide are turned off. When you have finished, select **Apply**.

Security Features Presets

The main Security Features can be turned off individually or the five system presets can be used:

- **Full UTM** should be chosen for networks that require full protection from FortiOS. UTM is the default setting.
- **WF** should be chosen for networks that require web filtering.
- **ATP** should be chosen for networks that require protection from viruses and other external threats.
- **NGFW** should be chosen for networks that require application control and protection from external attacks.
- **NGFW + ATP** should be chosen for networks that require protection from external threats and attacks.

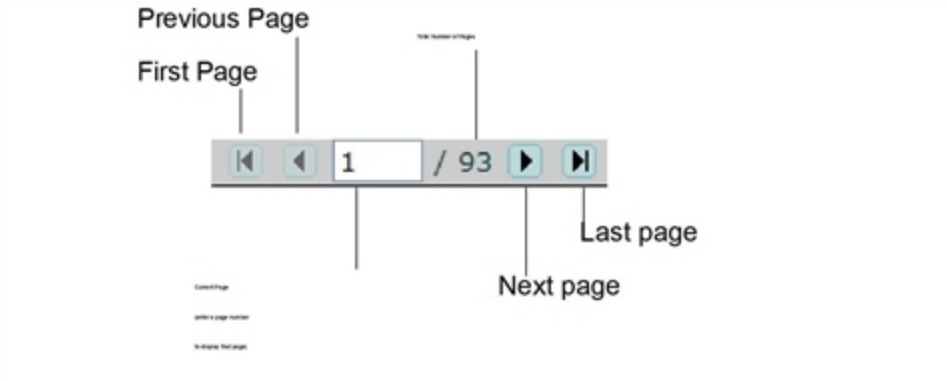
Information tables

Many of the web-based manager pages contain tables of information that you can filter to display specific information. Administrators with read and write access can define the filters.

Navigation

Some tables contain information and lists that span multiple pages. At the bottom of the page is the page navigation controls that enables you to move between pages.

Page controls



Adding filters to web-based manager lists

Filters are used to locate a specific set of information or content within multiple pages. These are especially useful in locating specific log entries. The specific filtering options vary, depending on the type of information in the log.

To create a filter, select **Filter Settings** or the filter icon in a column heading. When a filter is applied to a column, the filter icon becomes green. Filter settings are stored in the unit's configuration and will be maintained the next time that you access any list for which you have added filters.

Filtering variables can include: a numeric range (such as 25-50), an IP address or part of an address or any text string combination, including special characters.

Note that the filtering ignores characters following a "<" unless the followed by a space. For example, the filtering ignores `<string` but not `< string`. Filtering also ignores matched opening and closing (< and >) characters and any characters between them. For example, filtering will ignore `<string>`.

For columns that contain only specific content, such as log message severity, a list of terms is provided from which options can be selected.

Using column settings

Column settings are used to select the types of information which are displayed on a certain page. Some pages have a large amounts of information is available and not all content can be displayed on a single screen. Also, some pages may contain content that is not of use to you. Using column settings, you can display only that content which is important to your requirements.

To configure column settings, right-click the header of a column and select the columns you wish to view and de-select any you wish to hide. After you have finished making your selections, select **Apply** (you may need to scroll down the list to do so).

Any changes that you make to the column settings of a list are stored in the unit's configuration and will display the next time that you access the list. To return a page's columns to their default state, select **Reset All Columns**, located at the bottom of the **Column Settings** menu.

Text strings

The configuration of a FortiGate unit is stored in the FortiOS configuration database. To change the configuration, you can use the web-based manager or CLI to add, delete, or change configuration settings. These changes are stored in the database as you make them.

Individual settings in the configuration database can be text strings, numeric values, selections from a list of allowed options, or on/off (enable/disable) settings.

Entering text strings (names)

Text strings are used to name entities in the configuration. For example, the name of a firewall address, administrative user, and so on. You can enter any character in a FortiGate configuration text string except, to prevent Cross-Site Scripting (XSS) vulnerabilities, the following characters:

" (double quote), & (ampersand), ' (single quote), < (less than) and > (greater than)

Most web-based manager text string fields make it easy to add an acceptable number of characters and prevent you from adding the XSS vulnerability characters.

There is a different character limitation for VDOM names and hostnames. For both, the only legal characters are numbers (0-9), letters (a-z, A-Z), and special characters - and _.

From the CLI, you can also use the `tree` command to view the number of characters that are allowed in a name field. For example, firewall address names can contain up to 64 characters. When you add a firewall address to the web-based manager, you are limited to entering 64 characters in the firewall address name field. From the CLI you can enter the following `tree` command to confirm that the firewall address `name` field allows 64 characters.

```
config firewall address
   tree
   -- [address] --*name (64)
   |- subnet
   |- type
   |- start-ip
   |- end-ip
   |- fqdn (256)
```

```
|- cache-ttl (0,86400)
|- wildcard
|- comment (64 xss)
|- associated-interface (16)
+- color (0,32)
```

The `tree` command output also shows the number of characters allowed for other firewall address name settings. For example, the fully-qualified domain name (`fqdn`) field can contain up to 256 characters.

Entering numeric values

Numeric values set various sizes, rates, numeric addresses, and other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or, as in the case of MAC or IPv6 addresses, separated by colons (for example, the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again, such as MAC addresses) require hexadecimal numbers.

Most web-based manager numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the web-based manager and the CLI prevent you from entering invalid numbers.

Basic Administration

This section contains information about basic FortiGate administration that can be done after you have installed the unit in your network.

While this section mainly focuses on tasks done using the web-based manager, some tasks include instructions to use the command line interface (CLI). You can connect to the CLI using the CLI widget, FortiExplorer, or by connecting using a SSH or Telnet connection. For more information about the CLI, see the System Administration handbook.

The following topics are included in this section:

Registration
System Settings
Firmware
FortiGuard
FortiCloud
Administrators
Passwords
Configuration Backups

Registration

In order to have full access to Fortinet Support and FortiGuard Services, you must register your FortiGate unit.

Registering your FortiGate:

1. Go to **System > Dashboard > Status** and locate the **License Information** widget.
2. Select **Register**.
3. In the pop-up window, either use an existing Fortinet Support account or create a new one. Select your **Country** and **Reseller**.
4. Select **OK**.

System Settings

There are several system settings that should be configured once your FortiGate is installed.

Default administrator password

By default, your FortiGate has an administrator account set up with the username `admin` and no password. In order to prevent unauthorized access to the FortiGate, it is highly recommended that you add a password to this account.

To change the default password:

1. Go to **System > Admin > Administrators**.
2. Edit the **admin** account.
3. Select **Change Password**.

4. Leave **Old Password** blank, enter the **New Password** and re-enter the password for confirmation.
5. Select **OK**.

For details on selecting a password and password best practices, see Passwords on page 232.

Language

The default language of the web-based manager is English. To change the language, go to **System > Admin > Settings**. In the **Display Settings** section, select the language you want from the **Language** drop-down list. For best results, you should select the language that is used by the management computer.

Time and date

For effective scheduling and logging, the FortiGate system date and time should be accurate. You can either manually set the system date and time or configure the FortiGate unit to automatically keep its time correct by synchronizing with a Network Time Protocol (NTP) server.

The Network Time Protocol enables you to keep the FortiGate time in sync with other network systems. By enabling NTP on the FortiGate unit, FortiOS will check with the NTP server you select at the configured intervals. This will also ensure that logs and other time-sensitive settings on the FortiGate unit are correct.

The FortiGate unit maintains its internal clock using a built-in battery. At startup, the time reported by the FortiGate unit will indicate the hardware clock time, which may not be accurate. When using NTP, the system time might change after the FortiGate has successfully obtained the time from a configured NTP server.

By default, FortiOS has the daylight savings time configuration enabled. The system time must be manually adjusted after daylight saving time ends. To disable DST, enter the following command in the CLI:

```
config system global
     set dst disable
end
```

To set the date and time

1. Go to **System > Dashboard > Status** and locate the **System Information** widget.
2. Beside **System Time,** select **Change**.
3. Select your **Time Zone**.
4. Either select **Set Time** and manually set the system date and time, or select **Synchronize with NTP Server**. If you select synchronization, you can either use the default FortiGuard servers or specify a different server. You can also set the **Sync Interval**.
5. Select **OK**.

If you use an NTP server, you can identify a specific port/IP address for this self-originating traffic. The configuration is performed in the CLI with the command `set source-ip`. For example, to set the source IP of NTP to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config system ntp
   set ntpsyn enable
   set syncinterval 5
   set source-ip 192.168.4.5
end
```

Idle timeout

By default, the web-based manager disconnects administrative sessions if no activity occurs for five minutes. This prevents someone from using the web-based manager if the management PC is left unattended.

To change the idle timeout

1. Go to **System > Admin > Settings**.
2. In the **Administration Settings** section, enter the time in minutes in the **Idle Timeout** field
3. Select **Apply**.

Administrator password retries and lockout time

By default, the FortiGate unit includes set number of three password retries, allowing the administrator a maximum of three attempts to log into their account before they are locked out for a set amount of time (by default, 60 seconds).

The number of attempts can be set to an alternate value, as well as the default wait time before the administrator can try to enter a password again. You can also change this to further sway would-be hackers. Both settings are must be configured with the CLI

To configure the lockout options:

```
config system global
   set admin-lockout-threshold <failed_attempts>
   set admin-lockout-duration <seconds>
end
```

For example, to set the lockout threshold to one attempt and a five minute duration before the administrator can try again to log in enter the commands”

```
config system global
   set admin-lockout-threshold 1
   set admin-lockout-duration 300
end
```

Administrative port settings

In order to improve security, you can change the default port configurations for administrative connections to the FortiGate. When connecting to the FortiGate unit when the port has changed, the port must be included, such as `https://<ip_address>:<port>`. For example, if you are connecting to the FortiGate unit using port 99, the url would be `https://192.168.1.99:99`.

To configure the lockout options:

1. Go to **System > Admin > Settings**.
2. Under **Administrative Settings,** change the port numbers for HTTP, HTTPS, Telnet, and/or SSH as needed. You can also select **Redirect to HTTPS** in order to avoid HTTP being used for the administrators.

When you change to the default port number for HTTP, HTTPS, Telnet, or SSH, ensure that the port number is unique. If a conflict exists with a particular port, a warning message will appear.

Changing the host name

The host name of your FortiGate unit appears in the **Host Name** row, in the **System Information** widget. The host name also appears at the CLI prompt when you are logged in to the CLI and as the SNMP system name.

To change the host name on the FortiGate unit, in the **System Information** widget, select **Change** in the **Host Name** row. The only administrators that can change a FortiGate unit's host name are administrators whose admin profiles permit system configuration write access. If the FortiGate unit is part of an HA cluster, you should use a unique host name to distinguish the FortiGate unit from others in the cluster.

RAID disk configuration

The RAID disk is configured from the Disk Configuration page.

RAID level	Select the level of RAID. Options include: • **RAID-0** — (striping) better performance, no redundancy • **RAID-1** — (mirroring) half the storage capacity, with redundancy • **RAID-5** — striping with parity checking, and redundancy Available RAID level options depend on the available number of hard disks. Two or more disks are required for RAID 0 or RAID 1. Three or more disks are required for RAID 5. Changing the RAID level will erase any stored log information on the array, and reboot the FortiGate unit. The FortiGate unit will remain offline while it reconfigures the RAID array. When it reboots, the array will need to synchronize before being fully operational.
Status	The status, or health, of RAID array. This status can be one of: • **OK** — standard status, everything is normal. • **OK (Background-Synchronizing) (%)** — synchronizing the disks after changing RAID level, Synchronizing progress bar shows percent complete. • **Degraded** — One or more of the disks in the array has failed, been removed, or is not working properly. A warning is displayed about the lack of redundancy in this state. Also, a degraded array is slower than a healthy array. Select **Rebuild RAID** to fix the array. • **Degraded (Background-Rebuilding) (%)** — The same as degraded, but the RAID array is being rebuilt in the background. The array continues to be in a fragile state until the rebuilding is completed.
Size	The size of the RAID array in gigabytes (GB). The size of the array depends on the RAID level selected, and the number of disks in the array.
Rebuild RAID	Select to rebuild the array after a new disk has been added to the array, or after a disk has been swapped in for a failed disk. If you try to rebuild a RAID array with too few disks you will get a rebuild error. After inserting a functioning disk, the rebuild will start. This button is only available when the RAID array is in a degraded state and has enough disks to be rebuilt. You cannot restart a rebuild once a rebuild is already in progress. **Note:** If a disk has failed, the number of working disks may not be enough for the RAID level to function. In this case, replace the failed disk with a working disk to rebuild the RAID array.

Disk#	The disk's position in the array. This corresponds to the physical slot of the disk. If a disk is removed from the FortiGate unit, the disk is marked as not a member of the array and its position is retained until a new disk is inserted in that drive bay.
Status	The status of this disk. Options include OK, and unavailable. A disk is unavailable if it is removed or has failed.

Firmware

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, https://support.fortinet.com.

Before you install any new firmware, be sure to follow the steps below:

- Review the Release Notes for a new firmware release.
- Review the Supported Upgrade Paths document to make sure the upgrade from your current image to the desired new image is supported.
- Backup the current configuration, including local certificates. For more information, see Configuration Backups on page 233.
- Test the new firmware until you are satisfied that it applies to your configuration.

Installing new firmware without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin users and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

Backing up the current configuration

In case you need to restore your FortiGate configuration, you should always back up the configuration before installing new firmware.

To create a local backup:

1. Go to **System > Dashboard > Status** and locate the **System Information** widget.
2. Select **Backup** beside **System Configuration**.
3. Choose either **Local PC** or **USB Disk** to save the configuration file.
4. If desired, select **Encrypt configuration file**.
5. Select **Backup**.

Downloading firmware

Firmware images for all FortiGate units is available on the Fortinet Customer Support website, https://support.fortinet.com.

To download firmware

1. Log into the site using your user name and password.
2. Go to **Download > Firmware Images**.
3. A list of Release Notes is shown. If you have not already done so, download and review the Release Notes for the firmware you wish to upgrade your FortiGate unit to.
4. Select **HTTPS Download**.

Firmware can also be downloaded using FTP; however, as FTP is not an encrypted file transferring protocol, HTTPS downloading is recommended.

5. Navigate to find the folder for the firmware version you wish to use.
6. Select your FortiGate model from the list. If your unit is a FortiWiFi, be sure to get the appropriate firmware, which will have a filename starting with FWF.
7. Save the firmware image to your computer.

Testing new firmware before installing

FortiOS enables you to test a new firmware image by installing the firmware image from a system reboot and saving it to system memory. After completing this procedure, the FortiGate unit operates using the new firmware image with the current configuration. This new firmware image is not permanently installed. The next time the FortiGate unit restarts, it operates with the originally installed firmware image using the current configuration. If the new firmware image operates successfully, you can install it permanently using the procedure Upgrading the firmware - web-based manager on page 205 .

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9 or null modem cable. This procedure temporarily installs a new firmware image using your current configuration.

For this procedure, you must install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

To test the new firmware image

1. Connect to the CLI using a RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the FortiGate unit can connect to the TFTP server using the `execute ping` command.
5. Enter the following command to restart the FortiGate unit:

```
execute reboot
```

6. As the FortiGate unit reboots, press any key to interrupt the system startup. As the FortiGate unit starts, a series of system startup messages appears.
   When the following messages appears:

```
Press any key to display configuration menu....
```

7. Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must login and repeat the execute reboot command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
[Q]: Quit menu and continue to boot with default firmware.
    [H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get the new firmware image from the TFTP server.

   The following message appears:

   ```
   Enter TFTP server address [192.168.1.168]:
   ```

9. Type the address of the TFTP server and press **Enter**.

   The following message appears:

   ```
   Enter Local Address [192.168.1.188]:
   ```

10. Type an IP address of the FortiGate unit to connect to the TFTP server.

    The IP address must be on the same network as the TFTP server.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image file name and press **Enter**.

    The TFTP server uploads the firmware image file to the FortiGate unit and the following appears.

    ```
    Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
    ```

12. Type `R`.

    The FortiGate image is installed to system memory and the FortiGate unit starts running the new firmware image, but with its current configuration.

You can test the new firmware image as required. When done testing, you can reboot the FortiGate unit, and the FortiGate unit will resume using the firmware that was running before you installed the test firmware.

Upgrading the firmware - web-based manager

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

Always remember to back up your configuration before making any changes to the firmware.

To upgrade the firmware

1. Log into the web-based manager as the admin administrative user.
2. Go to **System > Dashboard > Status** and locate the **System Information** widget.
3. Beside **Firmware Version**, select **Update**.
4. Type the path and filename of the firmware image file, or select **Browse** and locate the file.
5. Select **OK**.

The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the FortiGate login. This process takes a few minutes.

Upgrading the firmware - CLI

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date. You can also use the CLI command `execute update-now` to update the antivirus and attack definitions. For more information, see the System Administration handbook.

Before you begin, ensure you have a TFTP server running and accessible to the FortiGate unit.

Always remember to back up your configuration before making any changes to the firmware.

To upgrade the firmware using the CLI

1. Make sure the TFTP server is running.
2. Copy the new firmware image file to the root directory of the TFTP server.
3. Log into the CLI.
4. Make sure the FortiGate unit can connect to the TFTP server.

   You can use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

   ```
   execute ping 192.168.1.168
   ```

5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

   ```
   execute restore image tftp <filename> <tftp_ipv4>
   ```

   Where `<name_str>` is the name of the firmware image file and `<tftp_ip4>` is the IP address of

the TFTP server. For example, if the firmware image file name is `image.out` and the IP address of the TFTP server is 192.168.1.168, enter:

```
execute restore image tftp image.out 192.168.1.168
```

The FortiGate unit responds with the message:

```
This operation will replace the current firmware version!
    Do you want to continue? (y/n)
```

6. Type `y`.
7. The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, and restarts. This process takes a few minutes.
8. Reconnect to the CLI.
9. Update antivirus and attack definitions, by entering:

```
execute update-now
```

Installing firmware from a system reboot using the CLI

There is a possibility that the firmware upgrade does not load properly and the FortiGate unit will not boot, or continuously reboots. If this occurs, it is best to perform a fresh install of the firmware from a reboot using the CLI.

This procedure installs a firmware image and resets the FortiGate unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or re-install the current firmware.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9, or null modem cable. This procedure reverts the FortiGate unit to its factory default configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

Before beginning this procedure, ensure you back up the FortiGate unit configuration.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

To install firmware from a system reboot

1. Connect to the CLI using the RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the internal interface is connected to the same network as the TFTP server.
5. To confirm the FortiGate unit can connect to the TFTP server, use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

6. Enter the following command to restart the FortiGate unit.

```
execute reboot
```

The FortiGate unit responds with the following message:

```
This operation will reboot the system!
Do you want to continue? (y/n)
```

7. Type `y`.

As the FortiGate unit starts, a series of system startup messages appears. When the following messages appears:

```
Press any key to display configuration menu.....
```

Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must log in and repeat the execute reboot command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
[Q]: Quit menu and continue to boot with default firmware.
[H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get to the new firmware image form the TFTP server.

The following message appears:

```
Enter TFTP server address [192.168.1.168]:
```

9. Type the address of the TFTP server and press **Enter**.

The following message appears:

```
Enter Local Address [192.168.1.188]:
```

10. Type an IP address the FortiGate unit can use to connect to the TFTP server. The IP address can be any IP address that is valid for the network the interface is connected to.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image filename and press **Enter**.

The TFTP server uploads the firmware image file to the FortiGate unit and a message similar to the following appears:

```
Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
```

12. Type `D`.

The FortiGate unit installs the new firmware image and restarts. The installation might take a few minutes to complete.

Reverting to a previous firmware version - web-based manager

The following procedures revert the FortiGate unit to its factory default configuration and deletes any configuration settings. If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Always remember to back up your configuration before making any changes to the firmware.

To revert to a previous firmware version

1. Go to **System > Dashboard > Status** and locate the **System Information widget**.
2. Beside **Firmware Version**, select **Update**.
3. Type the path and filename of the firmware image file, or select **Browse** and locate the file.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, reverts to the old firmware version, resets the configuration, restarts, and displays the FortiGate login. This process takes a few minutes.

Reverting to a previous firmware version - CLI

This procedure reverts the FortiGate unit to its factory default configuration and deletes IPS custom signatures, web content lists, email filtering lists, and changes to replacement messages.

Before beginning this procedure, it is recommended that you:

- back up the FortiGate unit system configuration using the command `execute backup config`
- back up the IPS custom signatures using the command `execute backup ipsuserdefsig`
- back up web content and email filtering lists

To use the following procedure, you must have a TFTP server the FortiGate unit can connect to.

To revert to a previous firmware version using the CLI

1. Make sure the TFTP server is running
2. Copy the firmware image file to the root directory of the TFTP server.
3. Log into the FortiGate CLI.
4. Make sure the FortiGate unit can connect to the TFTP server execute by using the `execute ping` command.
5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

   ```
   execute restore image tftp <name_str> <tftp_ipv4>
   ```

   Where `<name_str>` is the name of the firmware image file and `<tftp_ip4>` is the IP address of the TFTP server. For example, if the firmware image file name is `imagev28.out` and the IP address of the TFTP server is 192.168.1.168, enter:

   ```
   execute restore image tftp image28.out 192.168.1.168
   ```

   The FortiGate unit responds with this message:

```
This operation will replace the current firmware version!
    Do you want to continue? (y/n)
```

6. Type `y`.

   The FortiGate unit uploads the firmware image file. After the file uploads, a message similar to the following appears:

   ```
   Get image from tftp server OK.
   Check image OK.
   This operation will downgrade the current firmware version!
   Do you want to continue? (y/n)
   ```

7. Type `y`.
8. The FortiGate unit reverts to the old firmware version, resets the configuration to factory defaults, and restarts. This process takes a few minutes.
9. Reconnect to the CLI.
10. To restore your previous configuration, if needed, use the command:

    ```
    execute restore config <name_str> <tftp_ip4>
    ```

11. Update antivirus and attack definitions using the command:

    ```
    execute update-now.
    ```

Restore from a USB key - CLI

To restore configuration using the CLI

1. Log into the CLI.
2. Enter the following command to restore an unencrypted configuration file:

   ```
   exec restore image usb <filename>
   ```

   If your configuration file was encrypted, enter the following command:

   ```
   execute restore config usb-mode <password>
   ```

   The FortiGate unit responds with the following message:

   ```
   This operation will replace the current firmware version!
   Do you want to continue? (y/n)
   ```

3. Type `y`.

Configuration revision

The **Configuration Revisions** menu enables you to manage multiple versions of configuration files on models that have a 512 flash memory and higher. Revision control requires either a configured central management server or the local hard drive. The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears to tell you to do one of the following:

- enable central management
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configurations backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed in the **System Information** widget on the Dashboard.

Controlled upgrade

Using a controlled upgrade, you can upload a new version of the FortiOS firmware to a separate partition in the FortiGate memory for later upgrade. The FortiGate unit can also be configured so that when it is rebooted, it will automatically load the new firmware (CLI only). Using this option, you can stage a number of FortiGate units to do an upgrade simultaneously to all devices using FortiManager or script.

To load the firmware for later installation - web-based manager

1. Go to **System > Dashboard > Status**.
2. Under **System Information > Firmware Version**, select **Update**.
3. Type the path and filename of the firmware image file, or select **Browse** and locate the file.
4. Deselect the **Boot the New Firmware** option.
5. Select **OK**.

To load the firmware for later installation - CLI

```
execute restore secondary-image {ftp | tftp | usb}
```

To set the FortiGate unit so that when it reboots, the new firmware is loaded, use the CLI command…

```
execute set-next-reboot {primary | secondary}
```

… where `{primary | secondary}` is the partition with the preloaded firmware.

To trigger the upgrade using the web-based manager

1. Go to **System > Dashboard > Status**.
2. Under **System Information > Firmware Version**, select **Details**.
3. Select the check box for the new firmware version.
   The **Comments** column indicates which firmware version is the current active version.
4. Select **Upgrade** icon.

FortiGuard

The FortiGuard Distribution Network (FDN) of servers provides updates to antivirus, antispam and IPS definitions to your FortiGate unit. Worldwide coverage of FortiGuard services is provided by FortiGuard service points. FortiGuard Subscription Services provide comprehensive Unified Threat Management (UTM) security solutions to enable protection against content and network level threats.

The FortiGuard team can be found around the globe, monitoring virus, spyware and vulnerability activities. As vulnerabilities are found, signatures are created and pushed to the subscribed FortiGate units. The Global Threat Research Team enables Fortinet to deliver a combination of multi-layered security intelligence and provide true zero-day protection from new and emerging threats.The FortiGuard Network has data centers around the world located in secure, high availability locations that automatically deliver updates to the Fortinet security platforms to and protect the network with the most up-to-date information.

The FortiGuard services provide a number of services to monitor world-wide activity and provide the best possible security:

- **Intrusion Prevention** System (IPS)- The FortiGuard Intrusion Prevention System (IPS) uses a customizable database of more than 4000 known threats to stop attacks that evade conventional firewall defenses. It also provides behavior-based heuristics, enabling the system to recognize threats when no signature has yet been

developed. It also provides more than 1000 application identity signatures for complete application control.

- **Application Control** - Application Control allows you to identify and control applications on networks and endpoints regardless of port, protocol, and IP address used. It gives you unmatched visibility and control over application traffic, even traffic from unknown applications and sources.
- **AntiVirus** -The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content level threats. It employs advanced virus, spyware, and heuristic detection engines to prevent both new and evolving threats from gaining access to your network and protects against vulnerabilities.
- **Web Filtering** - Web Filtering provides Web URL filtering to block access to harmful, inappropriate, and dangerous web sites that may contain phishing/pharming attacks, malware such as spyware, or objectionable content that can expose your organization to legal liability. Based on automatic research tools and targeted research analysis, real-time updates enable you to apply highly-granular policies that filter web access based on 78 web content categories, over 45 million rated web sites, and more than two billion web pages - all continuously updated.
- **Vulnerability Scanning** - FortiGuard Services provide comprehensive and continuous updates for vulnerabilities, remediation, patch scan, and configuration benchmarks.
- **Email Filtering** - The FortiGuard Antispam Service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools on Fortinet appliances and agents, to detect and block a wide range of spam messages. Updates to the IP reputation and spam signature databases are provided continuously via the FDN.
- **Messaging Services** - Messaging Services allow a secure email server to be automatically enabled on your FortiGate unit to send alert email or send email authentication tokens. With the SMS gateway, you can enter phone numbers where the FortiGate unit will send the SMS messages. Note that depending on your carrier, there may be a slight time delay on receiving messages.
- **DNS and DDNS** - The FortiGuard DNS and DDNS services provide an efficient method of DNS lookups once subscribed to the FortiGuard network. This is the default option. The FortiGate unit connects automatically to the FortiGuard DNS server. If you do not register, you need to configure an alternate DNS server.

  Configure the DDNS server settings using the CLI commands:

```
config system fortiguard
   set ddns-server-ip
   set ddns-server-port
end
```

Support Contract and FortiGuard Subscription Services

The **Support Contract** and **FortiGuard Subscription Services** sections are displayed in abbreviated form within the **License Information** widget. A detailed version is available by going to **System > Config > FortiGuard**.

The Support Contract area displays the availability or status of your FortiGate unit's support contract. The status displays can be either **Unreachable, Not Registered,** or **Valid Contract**.

The FortiGuard Subscription Services area displays detailed information about your FortiGate unit's support contract and FortiGuard subscription services. On this page, you can also manually update the antivirus and IPS engines.

The status icons for each section Indicates the state of the subscription service. The icon corresponds to the availability description.

- **Gray (Unreachable)** – the FortiGate unit is not able to connect to service.
- **Orange (Not Registered)** – the FortiGate unit can connect, but not subscribed.
- **Yellow (Expired)** – the FortiGate unit had a valid license that has expired.

- **Green (Valid license)** – the FortiGate unit can connect to FDN and has a registered support contract. If the Status icon is green, the expiry date also appears.

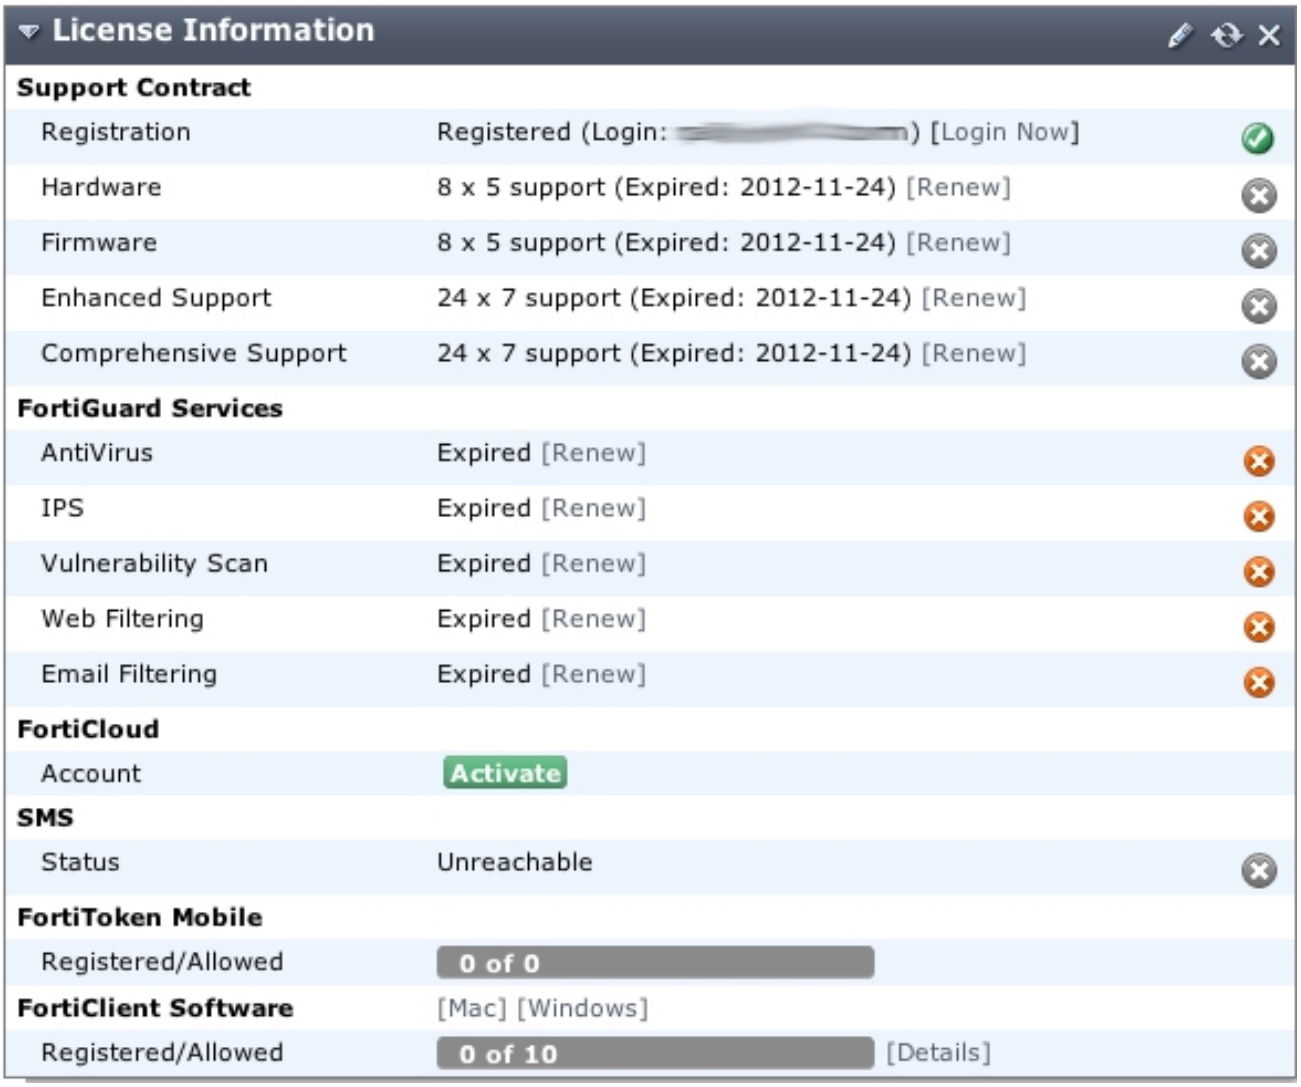
Verifying your Connection to FortiGuard

If you are not getting FortiGuard web filtering or antispam services, there are a few things to verify communication to the FortiGuard Distribution Network (FDN) is working. Before any troubleshooting, ensure that the FortiGate unit has been registered and you or your company, has subscribed to the FortiGuard services.

Verification - web-based manager

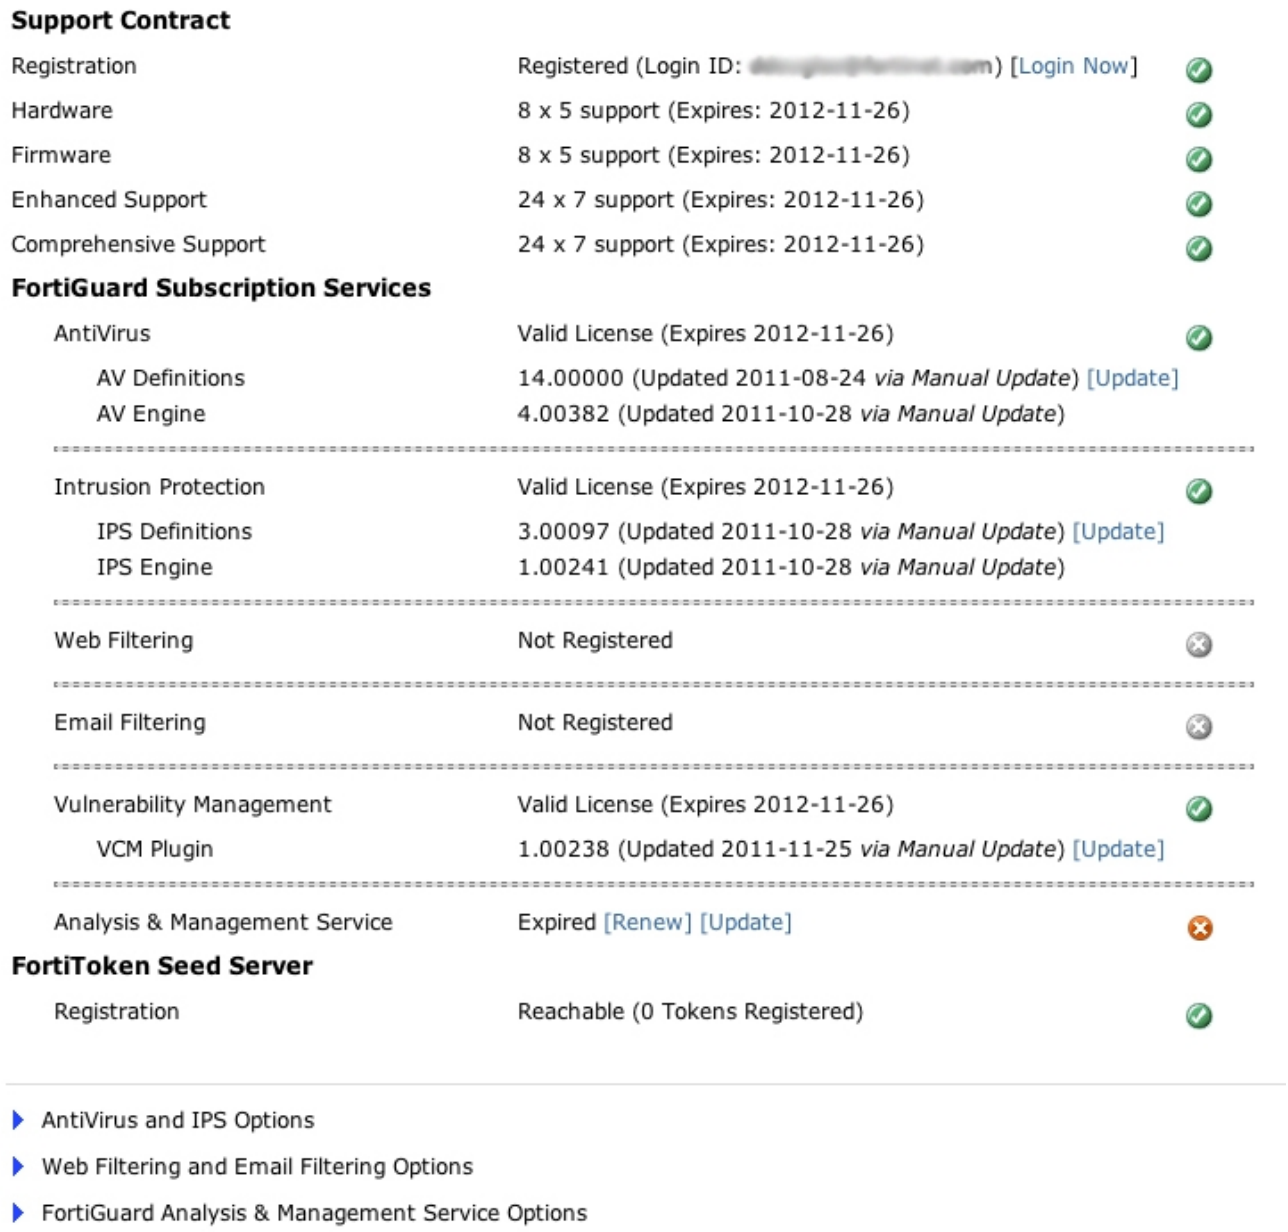
The simplest method to check that the FortiGate unit is communicating with the FDN, is to check the **License Information** dashboard widget. Any subscribed services should have a green check mark beside them indicating that connections are successful. Any other icon indicates a problem with the connection, or you are not subscribed to the FortiGuard services.

License Information widget showing FortiGuard availability



You can also view the FortiGuard connection status by going to **System > Config > FortiGuard**.

FortiGuard availability



Verification - CLI

You can also use the CLI to see what FortiGuard servers are available to your FortiGate unit. Use the following CLI command to ping the FDN for a connection:

```
ping guard.fortinet.net
```

You can also use diagnose command to find out what FortiGuard servers are available:

```
diagnose debug rating
```

From this command, you will see output similar to the following:

```
Locale : english
License : Contract
Expiration : Sun Jul 24 20:00:00 2011
Hostname : service.fortiguard.net
-=- Server List (Tue Nov 2 11:12:28 2010) -=-

IP Weight      RTT Flags  TZ   Packets   Curr Lost   Total Lost
69.20.236.180  0   10     -5   77200 0           42
69.20.236.179  0   12     -5   52514     0           34
66.117.56.42   0   32     -5   34390     0 62
80.85.69.38    50  164     0   34430     0           11763
208.91.112.194 81  223 D  -8   42530     0           8129
216.156.209.26 286 241 DI -8   55602     0          21555
```

An extensive list of servers are available. Should you see a list of three to five available servers, the FortiGuard servers are responding to DNS replies to service.FortiGuard.net, but the INIT requests are not reaching FDS services on the servers.

The rating flags indicate the server status:

D	Indicates the server was found via the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with 'D' and will be used first for INIT requests before falling back to the other servers.
I	Indicates the server to which the last INIT request was sent
F	The server has not responded to requests and is considered to have failed.
T	The server is currently being timed.

The server list is sorted first by weight and then the server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost, it will be resent to the next server in the list.

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a faraway server, the weight is not allowed to dip below a base weight, which is calculated as the difference in hours between the FortiGate unit and the server multiplied by 10. The further away the server is, the higher its base weight and the lower in the list it will appear.

Port assignment

FortiGate units contact the FortiGuard Distribution Network (FDN) for the latest list of FDN servers by sending UDP packets with typical source ports of 1027 or 1031, and destination ports of 53 or 8888. The FDN reply packets have a destination port of 1027 or 1031.

If your ISP blocks UDP packets in this port range, the FortiGate unit cannot receive the FDN reply packets. As a result, the FortiGate unit will not receive the complete FDN server list.

If your ISP blocks the lower range of UDP ports (around 1024), you can configure your FortiGate unit to use higher-numbered ports, using the CLI command…

```
config system global
   set ip-src-port-range <start port>-<end port>
```

```
end
```

…where the <start port> and <end port> are numbers ranging of 1024 to 25000.

For example, you could configure the FortiGate unit to not use ports lower than 2048 or ports higher than the following range:

```
config system global
   set ip-src-port-range 2048-20000
end
```

Trial and error may be required to select the best source port range. You can also contact your ISP to determine the best range to use. Push updates might be unavailable if:

- there is a NAT device installed between the unit and the FDN
- your unit connects to the Internet using a proxy server.

FortiCloud is a hosted security management and log retention service for FortiGate products. It gives you a centralized reporting, traffic analysis, configuration and log retention without the need for additional hardware and software.

Configuring Antivirus and IPS Options

Go to **System > Config > FortiGuard**, and expand the **AV and IPS Options** section to configure the antivirus and IPS options for connecting and downloading definition files.

Use override server address	Select to configure an override server if you cannot connect to the FDN or if your organization provides updates using their own FortiGuard server.
Allow Push Update	Select to allow updates sent automatically to your FortiGate unit when they are available
Allow Push Update status icon	The status of the FortiGate unit for receiving push updates: • **Gray (Unreachable)** - the FortiGate unit is not able to connect to push update service • **Yellow (Not Available)** - the push update service is not available with your current support license • **Green (Available)** - the push update service is allowed.
Use override push IP and Port	Available only if both **Use override server address** and **Allow Push Update** are enabled. Enter the IP address and port of the NAT device in front of your FortiGate unit. FDS will connect to this device when attempting to reach the FortiGate unit. The NAT device must be configured to forward the FDS traffic to the FortiGate unit on UDP port 9443.
Schedule Updates	Select this check box to enable updates to be sent to your FortiGate unit at a specific time. For example, to minimize traffic lag times, you can schedule the update to occur on weekends or after work hours. Note that a schedule of once a week means any urgent updates will not be pushed until the scheduled time. However, if there is an urgent update required, select the **Update Now** button.
Update Now	Select to manually initiate an FDN update.
Submit attack characteristics... (recommended)	Select to help Fortinet maintain and improve IPS signatures. The information sent to the FortiGuard servers when an attack occurs and can be used to keep the database current as variants of attacks evolve.

Manual updates

To manually update the signature definitions file, you need to first go to the Support web site at https://support.fortinet.com. Once logged in, select FortiGuard Service Updates from the Download area of the web page. The browser will present you the most current antivirus and IPS signature definitions which you can download.

Once downloaded to your computer, log into the FortiGate unit to load the definition file.

To load the definition file onto the FortiGate unit

1. Go to **System > Config > FortiGuard**.
2. Select the **Update** link for either **AV Definitions or IPS Definitions**.

3. Locate the downloaded file and select **OK**.

The upload may take a few minutes to complete.

Automatic updates

The FortiGate unit can be configured to request updates from the FortiGuard Distribution Network. You can configure this to be on a scheduled basis, or with push notifications.

Scheduling updates

Scheduling updates ensures that the virus and IPS definitions are downloaded to your FortiGate unit on a regular basis, ensuring that you do not forget to check for the definition files yourself. As well, by scheduling updates during off-peak hours, such as evenings or weekends, when network usage is minimal, ensures that the network activity will not suffer from the added traffic of downloading the definition files.

If you require the most up-to-date definitions as viruses and intrusions are found in the wild, the FortiGuard Distribution Network can push updates to the FortiGate units as they are developed. This ensures that your network will be protected from any breakouts of a virus within the shortest amount of time, minimizing any damaging effect that can occur. Push updates require that you have registered your FortiGate unit.

Once push updates are enabled, the next time new antivirus or IPS attack definitions are released, the FDN notifies all the FortiGate unit that a new update is available. Within 60 seconds of receiving a push notification, the unit automatically requests the update from the FortiGuard servers.

To enable scheduled updates - web-based manager

1. Go to **System > Config > FortiGuard**.
2. Click the Expand Arrow for **AV and IPS Options**.
3. Select the **Scheduled Update** check box.
4. Select the frequency of the updates and when within that frequency.
5. Select **Apply**.

To enable scheduled updates - CLI

```
config system autoupdate schedule
   set status enable
   set frequency {every | daily | weekly}
   set time <hh:mm>
   set day <day_of_week>
end
```

Push updates

Push updates enable you to get immediate updates when new virus or intrusions have been discovered and new signatures are created. This ensures that when the latest signature is available it will be sent to the FortiGate.

When a push notification occurs, the FortiGuard server sends a notice to the FortiGate unit that there is a new signature definition file available. The FortiGate unit then initiates a download of the definition file, similar to the scheduled update.

To ensure maximum security for your network, you should have a scheduled update as well as enable the push update, in case an urgent signature is created, and your cycle of the updates only occurs weekly.

To enable push updates - web-based manager

1. Go to **System > Config > FortiGuard**.
2. Click the Expand Arrow for **AV and IPS Options**.
3. Select **Allow Push Update**.
4. Select **Apply**.

To enable push updates - CLI

```
config system autoupdate push-update
   set status enable
end
```

Push IP override

If the FortiGate unit is behind another NAT device (or another FortiGate unit), to ensure it receives the push update notifications, you need to use an override IP address for the notifications. To do this, you create a virtual IP to map to the external port of the NAT device.

Generally speaking, if there are two FortiGate devices as in the diagram below, the following steps need to be completed on the FortiGate NAT device to ensure the FortiGate unit on the internal network receives the updates:

- Add a port forwarding virtual IP to the FortiGate NAT device that connects to the Internet by going to **Firewall Objects > Virtual IP**.
- Add a security policy to the FortiGate NAT device that connects to the Internet that includes the port forwarding virtual IP.
- Configure the FortiGate unit on the internal network with an override push IP and port.

On the FortiGate internal device, the virtual IP is entered as the **Use push override IP** address.

To enable push update override- web-based manager

1. Go to **System > Config > FortiGuard**.
2. Click the Expand Arrow for **AV and IPS Options**.
3. Select **Allow Push Update**.
4. Select **Use push override IP**.
5. Enter the virtual IP address configured on the NAT device.
6. Select **Apply**.

To enable push updates - CLI

```
config system autoupdate push-update
   set status enable
   set override enable
   set address <vip_address>
end
```

Configuring Web Filtering and Email Filtering Options

Go to **System > Config > FortiGuard**, and expand arrow to view **Web Filtering and Email Filtering Options** for setting the size of the caches and ports used.

Web Filter cache TTL	Set the Time To Live value. This is the number of seconds the FortiGate unit will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate unit will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
Antispam cache TTL	Set the Time To Live value. This is the number of seconds the FortiGate unit will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate unit will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
Port Section	Select the port assignments for contacting the FortiGuard servers. Select the **Test Availability** button to verify the connection using the selected port.
To have a URL's category rating re-evaluated, please click here	Select to re-evaluate a URL's category rating on the FortiGuard Web Filter service.

Email filtering

The FortiGuard data centers monitor and update email databases of known spam sources. With FortiGuard Antispam enabled, the FortiGate unit verifies incoming email sender address and IPs against the database, and take the necessary action as defined within the antivirus profiles.

Spam source IP addresses can also be cached locally on the FortiGate unit, providing a quicker response time, while easing load on the FortiGuard servers, aiding in a quicker response time for less common email address requests.

By default, the antispam cache is enabled. The cache includes a time-to-live value, which is the amount of time an email address will stay in the cache before expiring. You can change this value to shorten or extend the time between 300 and 86400 seconds.

To modify the antispam filter cache size - web-based manager

1. Go to **System > Config > FortiGuard**.
2. Click the Expand Arrow for **Web Filtering and Email Filtering Options**.
3. Enter the TTL value for the **antispam cache**.
4. Select **Apply**.

To modify the web filter cache size - CLI

```
config system fortiguard
   set antispam-cache-ttl <integer>
end
```

Further antispam filtering options can be configured to block, allow or quarantine, specific email addresses. These configurations are available through the **Security Profiles > Antispam** menu. For more information, see the Security Profiles handbookchapter.

Online Security Tools

The FortiGuard online center provides a number of online security tools that enable you to verify or check ratings of web sites, email addresses as well as check file for viruses:

- **URL lookup** - By entering a web site address, you can see if it has been rated and what category and classification it is filed as. If you find your web site or a site you commonly go to has been wrongly categorized, you can use this page to request that the site be re-evaluated.
  http://www.fortiguard.com/webfiltering/webfiltering.html
- **IP and signature lookup** - The IP and signature lookup enables you to check whether an IP address is blacklisted in the FortiGuard IP reputation database or whether a URL or email address is in the signature database.
  http://www.fortiguard.com/antispam/antispam.html
- **Online virus scanner** - If you discover a suspicious file on your machine, or suspect that a program you downloaded from the Internet might be malicious you can scan it using the FortiGuard online scanner. The questionable file can be uploaded from your computer to a dedicated server where it will be scanned using FortiClient Antivirus. Only one file of up to 1 MB can be checked at any one time. All files will be forwarded to our research labs for analysis.
  http://www.fortiguard.com/antivirus/virus_scanner.html
- **Malware removal tools** - Tools have been developed by FortiGuard Labs to disable and remove the specific malware and related variants. Some tools have been developed to remove specific malware, often tough to remove. A universal cleaning tool, FortiCleanup, is also available for download.
  The FortiCleanup is a tool developed to identify and cleanse systems of malicious rootkit files and their associated malware. Rootkits consist of code installed on a system with kernel level privileges, often used to hide malicious files, keylog and thwart detection / security techniques. The aim of this tool is to reduce the effectiveness of such malware by finding and eliminating rootkits. The tool offers a quick memory scan as well as a full system scan. FortiCleanup will not only remove malicious files, but also can cleanse registry entries, kernel module patches, and other tricks commonly used by rootkits - such as SSDT hooks and process enumeration hiding.
  A license to use these applications is provided free of charge, courtesy of Fortinet.
  http://www.fortiguard.com/antivirus/malware_removal.html

FortiCloud

FortiCloud (formerly known as FAMS) is a hosted security management and log retention service for FortiGate devices. It gives you centralized reporting, traffic analysis, configuration management and log retention without the need for additional hardware and software.

FortiGate models 800 and above do not support the FortiCloud service.

FortiCloud offers a wide range of features:

- **Simplified central management** - FortiCloud provides a central web-based management console to manage individual or aggregated FortiGate and FortiWiFi devices. Adding a device to the FortiCloud management subscription is straightforward and provides detailed traffic and application visibility across the whole network.

- **Hosted log retention with large default storage allocated** - Log retention is an integral part of any security and compliance program but administering a separate storage system is burdensome. FortiCloud takes care of this automatically and stores the valuable log information in the cloud. Each device is allowed up to 200Gb of log retention storage. Different types of logs can be stored including Traffic, System Events, Web, Applications and Security Events.
- **Monitoring and alerting in real time** - Network availability is critical to a good end-user experience. FortiCloud enables you to monitor your FortiGate network in real time with different alerting mechanisms to pinpoint potential issues. Alerting mechanisms can be delivered via email.
- **Customized or pre-configured reporting and analysis tools** - Reporting and analysis are your eyes and ears into your network's health and security. Pre-configured reports are available, as well as custom reports that can be tailored to your specific reporting and compliance requirements. For example, you may want to look closely at application usage or web site violations. The reports can be emailed as PDFs and can cover different time periods.
- **Maintain important configuration information uniformly** - The correct configuration of the devices within your network is essential to maintaining an optimum performance and security posture. In addition, maintaining the correct firmware (operating system) level allows you to take advantage of the latest features.
- **Service security** - All communication (including log information) between the devices and the clouds is encrypted. Redundant data centers are always used to give the service high availability. Operational security measures have been put in place to make sure your data is secure — only you can view or retrieve it.

Registration and Activation

Before you can activate a FortiCloud account, you must first register your device.

FortiCloud accounts can be registered manually through the FortiCloud website, https://www.forticloud.com, but you can easily register and activate your account directly within your FortiGate unit. Your registration process will vary somewhat, depending on which firmware version and device you have.

FortiGate models 300 and below, all FortiWiFi units

1. On your device's dashboard, in the License Information widget, select the green **Activate** button in the FortiCloud section.
2. A dialogue asking you to register your FortiCloud account will appear. Enter your information, view and accept the Terms and Conditions and select **Create Account**.
3. A second dialogue window will appear, asking you to enter your information to confirm your account. This will send a confirmation email to your registered email. The dashboard widget will update to show that confirmation is required.
4. Open your email, and follow the confirmation link contained in it.

A FortiCloud page will open, stating that your account has been confirmed. The Activation Pending message on the dashboard will change to state the type of account you have ('1Gb Free' or '200Gb Subscription'), and will now provide a link to the FortiCloud portal.

FortiGate models 600 to 800

For 600 through 800, FortiCloud registration must be done through the FortiGate CLI Console.

Enabling logging to FortiCloud

1. Go to **Log & Report > Log Config > Log Settings**.
2. Enable **Send Logs to FortiCloud.**
3. Select **Test Connectivity** to ensure that your FortiGate can connect to the registered FortiCloud account.

Logging into the FortiCloud portal

Once logging has been configured and you have registered your account, you can log into the FortiCloud portal and begin viewing your logging results. There are two methods to reach the FortiCloud portal:

- If you have direct networked access to the FortiGate unit, you can simply open your Dashboard and check the License Information widget. Next to the current FortiCloud connection status will be a link to reach the FortiCloud Portal.
- If you do not currently have access to the FortiGate's interface, you can visit the FortiCloud website (https://forticloud.com) and log in remotely, using your email and password. It will ask you to confirm the FortiCloud account you are connecting to and then you will be granted access. Connected devices can be remotely configured using the Scripts page in the Management Tab, useful if an administrator may be away from the unit for a long period of time.

Upgrading to a 200Gb subscription

Upgrading your subscription is simple but must be done through the FortiGate unit, as the storage contract is allocated based on devices rather than user accounts.

1. Open the FortiGate Dashboard.
2. In the License Information widget, select **Upgrade** next to 'Type' in the FortiCloud section.
3. A new window will open, showing the Fortinet Support portal. Follow the on-screen instructions to register your contract.
4. Wait approximately 10 minutes for the contract to be applied and then visit your Dashboard.

In the License Information widget, Type will have changed from 'Free' to 'Subscribed'. Your maximum listed storage will also have updated.

Cloud Sandboxing

FortiCloud can be used for automated sample tracking, or sandboxing, for files from a FortiGate unit. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database. This feature was formerly known as FortiGuard Analytics.

Cloud sandboxing is configured by going to **System > Config > FortiSandbox**. After enabling FortiSandbox, select **Cloud Sandbox (FortiCloud).**

Sandboxing results will be shown in a new tab called **AV Submissions** in the FortiCloud portal. This tab will only appear after a file has been sent for sandboxing.

Administrators

By default, the FortiGate unit has a super administrator called "admin". This user login cannot be deleted and always has ultimate access over the FortiGate unit. Additional administrators can be added for various functions, each with a unique username, password, and set of access privileges.

There are two levels of administrator accounts; regular administrators and system administrators. Regular administrators are administrators with any admin profile other than the default super_admin. System administrators are administrators that are assigned the super_admin profile, which has the highest level of access.

Adding administrators

The name of the administrator should not contain the characters <> () #" '. Using these characters in the administrator account name can result in a cross site scripting (XSS) vulnerability.

Only the default ”admin” account or an administrator with read-write access control to add new administrator accounts and control their permission levels can create a new administrator account. If you log in with an administrator account that does not have the super_admin admin profile, the administrators list will show only the administrators for the current virtual domain.

When adding administrators, you are setting up the administrator’s user account. An administrator account comprises of an administrator’s basic settings as well as their access profile. The access profile is a definition of what the administrator is capable of viewing and editing.

To add an administrator - web-based manager

1. Go to **System > Admin > Administrators**.
2. Select **Create New**.
3. Enter the administrator name.
4. Select the type of account it will be. If you select **Remote**, the FortiGate unit can reference a RADIUS, LDAP or TACAS+ server.
5. When selecting **Remote** or **PKI** accounts, select the User Group the account will access.
   For information on logging in using remote authentication servers, see the User Authentication Guide. For an example of setting up a user with LDAP, see LDAP Admin Access and Authorization on page 223
6. Enter the password for the user.
   This may be a temporary password that the administrator can change later. Passwords can be up to 256 characters in length. For more information on passwords, see Passwords on page 232.
7. Select **OK**.

To add an administrator - CLI

```
config system admin
   edit <admin_name>
      set password <password>
      set accprofile <profile_name>
end
```

LDAP Admin Access and Authorization

You can use the LDAP server as a means to add administrative users, saving the time to add users to the FortiGate unit administrator list. After configuring, any user within the selected LDAP group server can automatically log into the FortiGate unit as an adm i st rat or. Ensure that the admin profile is the correct level of access, or the users within the LDAP group are the only ones authorized to configure or modify the configuration of the FortiGate unit.

To do this, requires three steps:

- configure the LDAP server
- add the LDAP server to a user group
- configure the administrator account

Configure the LDAP server

First set up the LDAP server as you normally would, and include a group to bind to.

To configure the LDAP server - web-based manager

1. Go to **User & Device > Remote > LDAP** and select **Create New**.
2. Enter a **Name** for the server.
3. Enter the **Server IP** address or name.
4. Enter the **Common Name Identifier** and **Distinguished Name**.
5. Set the **Bind Type to Regular** and enter the **User DN** and **Password**.
6. Select **OK**.

To configure the LDAP server - CLI

```
config user ldap
   edit <ldap_server_name>
      set server <server_ip>
      set cnid cn
      set dn DC=XYZ,DC=COM
      set type regular
      set username CN=Administrator,CN=Users,DC=XYZ,DC=COM
      set password <password>
      set member-attr <group_binding>
end
```

Add the LDAP server to a user group

Next, create a user group that will include the LDAP server that was created above.

To create a user group - web-based manager

1. Go to **User & Device > User Group > User Group** and select **Create New**.
2. Enter a **Name** for the group.
3. In the section labelled **Remote authentication servers**, select **Add**.
4. Select the **Remote Server** from the drop-down list.
5. Select **OK**.

To create a user group - CLI

```
config user group
   edit <group_name>
      config match
         edit 1
            set server-name <LDAP_server>
            set group-name <group_name>
```

```
      end
   end
```

Configure the administrator account

Now you can create a new administrator, where rather than entering a password, you will use the new user group and the wildcard option for authentication.

To create an administrator - web-based manager

1. Go to **System > Admin > Administrators** and select **Create New**.
2. In the **Administrator** field, enter the name for the administrator.
3. For **Type**, select **Remote**.
4. Select the **User Group** created above from the drop-down list.
5. Select **Wildcard**.
6. The Wildcard option allows for LDAP users to connect as this administrator.
7. Select an **Admin Profile**.
8. Select **OK**.

To create an administrator - CLI

```
config system admin
   edit <admin_name>
      set remote-auth enable
      set accprofile super_admin
      set wildcard enable
      set remote-group ldap
   end
```

Monitoring administrators

You can view the administrators logged in using the **System Information** widget on the Dashboard. On the widget is the **Current Administrator** row that shows the administrator logged in and the total logged in. Selecting **Details** displays the administrators), where they are logging in from and how (CLI, web-based manager) and when they logged in.

You are also able to monitor the activities the administrators perform on the FortiGate unit using the logging of events. Event logs include a number of options to track configuration changes.

To set logging - web-based manager

1. Go to **Log & Report > Log Config > Log Settings**.
2. Under **Event Logging**, ensure **System activity event** is selected.
3. Select **Apply**.

To set logging - CLI

```
config log eventfilter
   set event enable
   set system enable
end
```

To view the logs go to **Log & Report > Event Log**.

Administrator profiles

Administer profiles define what the administrator user can do when logged into the FortiGate unit. When you set up an administrator user account, you also assign an administrator profile, which dictates what the administrator user will see. Depending on the nature of the administrator's work, access level or seniority, you can allow them to view and configure as much, or as little, as required.

super_admin profile

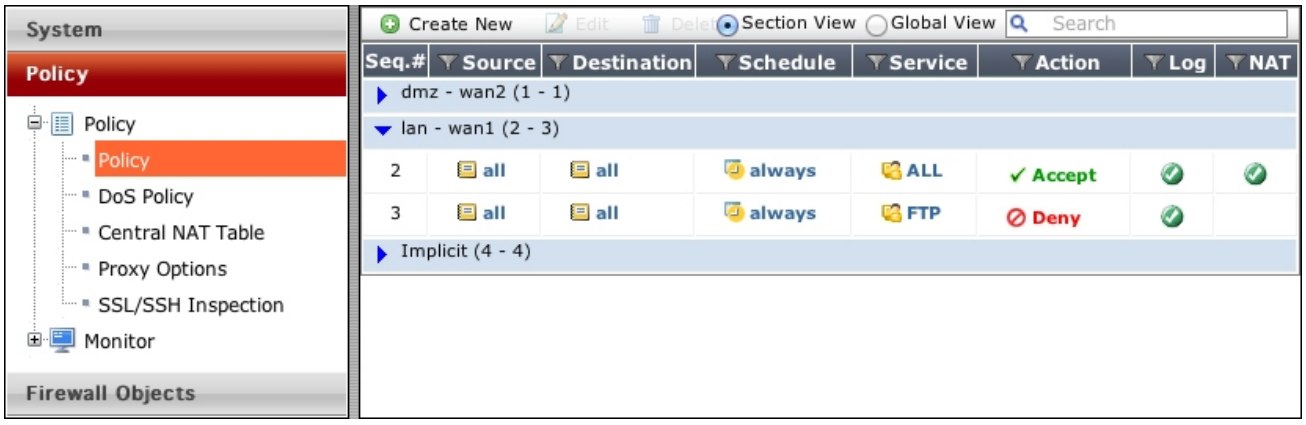
The super_admin administrator is the administrative account that the primary administrator should have to log into the FortiGate unit. The profile can not be deleted or modified to ensure there is always a method to administer the FortiGate unit.This user profile has access to all components of FortiOS, including the ability to add and remove other system administrators. For some administrative functions, such as backing up and restoring the configuration using SCP, super_admin access is required.

Creating profiles

To configure administrator profiles go to **System > Admin > Admin Profiles**. You can only assign one profile to an administrator user.

On the **New Admin Profile** page, you define the components of FortiOS that will be available to view and/or edit. For example, if you configure a profile so that the administrator can only access the firewall components, when an administrator with that profile logs into the FortiGate unit, they will only be able to view and edit any firewall components including policies, addresses, schedules and any other settings that directly affect security policies.

The view of an administrator with firewall-only access



Global and vdom profiles

By default, when you add a new administrative profile, it is set to have a vdom scope. That is, only the super_admin has a global profile that enables configuration of the entire FortiGate unit.

There may be instances where additional global administrative profiles may be required. To add more global profiles, use the following CLI command to set or change an administrative profile to be global.

```
config system accprofile
```

```
    set scope global
      ...
end
```

Once the scope is set, you can enable the read and read/write settings.

Regular (password) authentication for administrators

You can use a password stored on the local FortiGate unit to authenticate an administrator. When you select **Regular** for **Type**, you will see **Local** as the entry in the **Type** column when you view the list of administrators.

Management access

Management access defines how administrators are able to log on to the FortiGate unit to perform management tasks such as configuration and maintenance. Methods of access can include local access through the console connection or remote access over a network or modem interface using various protocols including Telnet and HTTPS.

You can configure management access on any interface in your VDOM. In NAT mode, the interface IP address is used for management access. In transparent mode, you configure a single management IP address that applies to all interfaces in your VDOM that permit management access. The FortiGate unit also uses this IP address to connect to the FDN for virus and attack updates.

The system administrator (admin) can access all VDOMs, and create regular administrator accounts. A regular administrator account can access only the VDOM to which it belongs and the management computer must connect to an interface in that VDOM. In both cases, the management computer must connect to an interface that permits management access and its IP address must be on the same network. Management access can be via HTTP, HTTPS, Telnet, or SSH sessions, if those services are enabled on the interface. HTTPS and SSH are preferred as they are more secure.

You can allow remote administration of the FortiGate unit. However, allowing remote administration from the Internet could compromise the security of the FortiGate unit. You should avoid this unless it is required for your configuration. The following precautions can be taken to improve the security of a FortiGate unit that allows remote administration from the Internet:

- Use secure administrative user passwords.
- Change these passwords regularly.
- Enable two-factor authentication for administrators.
- Enable secure administrative access to this interface using only HTTPS or SSH.
- Use Trusted Hosts to limit where the remote access can originate from.
- Do not change the system idle timeout from the default value of 5 minutes.

Security Precautions

One potential point of a security breach is at the management computer. Administrators who leave their workstations for a prolonged amount of time while staying logged into the web-based manager or CLI leave the firewall open to malicious intent.

Preventing unwanted login attempts

Setting trusted hosts for an administrator limits what computers an administrator can log in from, causing the FortiGate unit to only accept the administrator's login from the configured IP address. Any attempt to log in with the same credentials from any other IP address will be dropped.

Trusted hosts are configured when adding a new administrator by going to **System > Admin > Administrators** in the web-based manager or `config system admin` in the CLI.

To ensure the administrator has access from different locations, you can enter up to ten IP addresses, though ideally this should be kept to a minimum. For higher security, use an IP address with a net mask of 255.255.255.255, and enter an IP address (non-zero) in each of the three default trusted host fields. Also ensure all entries contain actual IP addresses, not the default 0.0.0.0.

The trusted hosts apply to the web-based manager, ping, SNMP, and the CLI when accessed through Telnet or SSH. CLI access through the console port is not affected.

Prevent multiple admin sessions

Multiple admin sessions can occur when multiple users access the FortiGate using the same admin account. By default, the FortiGate unit enables multiple logins of administrators using the same login credentials from different locations. To control admin log ins, and minimize the potential of configuration collisions, you can disable concurrent admin sessions. When disabled, only one user can use the admin account at a time. When a second admin attempts to connect, connection is denied with a message that the login attempt failed.

To disable concurrent admin sessions, enter the following command in the CLI:

```
config system global
   set admin-concurrent disable
end
```

On 2U FortiGate units, this option is also available in the Web-Based Manager by going to **System > Admin > Settings** and select **Allow each admin to log in with multiple sessions**.

Segregated administrative roles

To minimize the effect of an administrator causing errors to the FortiGate configuration and possibly jeopardizing the network, create individual administrative roles where none of the administrators have super-admin permissions. For example, one admin account is used solely to create security policies, another for users and groups, another for VPN, and so on.

Disable admin services

On untrusted networks, turn off the weak administrative services such as Telnet and HTTP. With these services, passwords are passed in the clear, not encrypted. These services can be disabled by going to **System > Network > Interface** and unselecting the required check boxes.

SSH login time out

When logging into the console using SSH, the default time of inactivity is 120 seconds (2 minutes) to successfully log into the FortiGate unit. To enhance security, you can configure the time to be shorter. Using the CLI, you can change the length of time the command prompt remains idle before the FortiGate unit will log the administrator out. The range can be between 10 and 3600 seconds.

To set the logout time enter the following commands:

```
config system global
   set admin-ssh-grace-time <number_of_seconds>
end
```

Idle time-out

To avoid the possibility of an administrator walking away from the management computer and leaving it exposed to unauthorized personnel, you can add an idle time-out that will automatically log the user out if the web-based manager is not used for a specified amount of time. This will cause the administrator to log in to the device again in order to continue their work.

The time-out can be set as high as 480 minutes, or eight hours, although this is not recommend.

To set the idle time out - web-based manager

1. Go to **System > Admin > Settings**.
2. In the **Administration Settings**, enter the amount of time the Administrator login can remain idol in the **Idle Timeout** field.
3. Select **Apply**.

To set the idle time out - CLI

```
config system global
   set admintimeout <minutes>
end
```

HTTPS redirect

When selecting port numbers for various protocols, you can also enable or disable the Redirect to HTTPS option. When enabled, if you select the Administrative Access for an interface to be only HTTP, HTTPS will automatically be enabled, allowing the administrator access with either HTTP or HTTPS. The administrator can then log in using HTTPS for better security.

Note that if an SSL VPN is also configured for the same port, the SSL connection is over the HTTPS protocol. In these situations, the FortiGate unit will not redirect an HTTP address to the SSL VPN HTTPS address. Ideally, the administrator should not have the management address and an SSL VPN portal on the same interface.

Log in/out warning message

For administrators logging in and out of the FortiGate unit, you can include a login disclaimer. This disclaimer provides a statement that must be accepted or declined where corporations are governed by strict usage policies for forensics and legal reasons.

The disclaimer is enabled through the CLI.

To disable an interface:

```
config system global
   set pre-login-banner enable
   set post-login-banner enable
end
```

When set, once the administrator enters their user name and password, the disclaimer appears. They must select either Accept or Decline to proceed. When the post login is enabled, once the administrator logs out they are presented with the same message.

The banner is a default message that you can customize by going to **System > Config > Replacement Messages**. Select **Extended View** to see the **Admin** category and messages.

Disable the console interface

To prevent any unwanted login attempts using the COM communication port, you can disable login connections to the FortiGate unit.

This command is specifically for the COM port. You can still use FortiExplorer to connect and configure the FortiGate unit if required.

To disable an interface:

```
config system console
   set login disable
end
```

Disable interfaces

If any of the interfaces on the FortiGate unit are not being used, disable traffic on that interface. This avoids someone plugging in network cables and potentially causing network bypass or loop issues.

To disable an interface - web-based manager

1. Go to **System > Network > Interface**.
2. Select the interface from the list and select **Edit**.
3. For **Administrative Access**, select **Down**.
4. Select **OK**.

To disable an interface - CLI

```
config system interface
   edit <inerface_name>
      set status down
end
```

RADIUS authentication for administrators

Remote Authentication and Dial-in User Service (RADIUS) servers provide authentication, authorization, and accounting functions. FortiGate units use the authentication and authorization functions of the RADIUS server. To use the RADIUS server for authentication, you must configure the server before configuring the FortiGate users or user groups that will need it.

If you have configured RADIUS support and a user is required to authenticate using a RADIUS server, the FortiGate unit sends the user's credentials to the RADIUS server for authentication. If the RADIUS server can authenticate the user, the user is successfully authenticated with the FortiGate unit. If the RADIUS server cannot authenticate the user, the FortiGate unit refuses the connection.

If you want to use a RADIUS server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure the FortiGate unit to access the RADIUS server
- create the RADIUS user group

- configure an administrator to authenticate with a RADIUS server.

Configuring LDAP authentication for administrators

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, printers, etc.

If you have configured LDAP support and an administrator is required to authenticate using an LDAP server, the FortiGate unit contacts the LDAP server for authentication. If the LDAP server cannot authenticate the administrator, the FortiGate unit refuses the connection.

If you want to use an LDAP server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure an LDAP server
- create an LDAP user group
- configure an administrator to authenticate with an LDAP server.

To view the LDAP server list, go to **User & Device > Remote > LDAP**.

For more information, see LDAP Admin Access and Authorization on page 223 .

TACACS+ authentication for administrators

Terminal Access Controller Access-Control System (TACACS+) is a remote authentication protocol that provides access control for routers, network access servers, and other network computing devices via one or more centralized servers.

If you have configured TACACS+ support and an administrator is required to authenticate using a TACACS+ server, the FortiGate unit contacts the TACACS+ server for authentication. If the TACACS+ server cannot authenticate the administrator, the connection is refused by the FortiGate unit.

If you want to use an TACACS+ server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure the FortiGate unit to access the TACACS+ server
- create a TACACS+ user group
- configure an administrator to authenticate with a TACACS+ server.

PKI certificate authentication for administrators

Public Key Infrastructure (PKI) authentication uses a certificate authentication library that takes a list of peers, peer groups, and user groups and returns authentication successful or denied notifications. Users only need a valid certificate for successful authentication; no username or password is necessary.

To use PKI authentication for an administrator, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure a PKI user
- create a PKI user group
- configure an administrator to authenticate with a PKI certificate.

Passwords

Using secure admin passwords are vital for preventing unauthorized access to your FortiGate unit. When changing the password, consider the following to ensure better security:

- Do not make passwords that are obvious, such as the company name, administrator names, or other obvious word or phrase.
- Use numbers in place of letters, for example, `passw0rd`. Alternatively, spell words with extra letters, for example, **password**.
- Administrative passwords can be up to 64 characters.
- Include a mixture of letters, numbers, and upper and lower case.
- Use multiple words together, or possibly even a sentence, for example keytothehighway.
- Use a password generator.
- Change the password regularly and always make the new password unique and not a variation of the existing password, such as changing from `password` to `password1`.
- Write the password down and store it in a safe place away from the management computer, in case you forget it or ensure that at least two people know the password in the event that one person becomes ill, is away on vacation or leaves the company. Alternatively, have two different admin logins.

Password policy

The FortiGate unit includes the ability to enforce a password policy for administrator login. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain non-alphanumeric characters (!, @, #, $, %, ^, &, *, ().
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

To apply a password policy - web-based manager

1. Go to **System > Admin > Settings**.
2. Select **Enable Password Policy** and configure the settings as required.

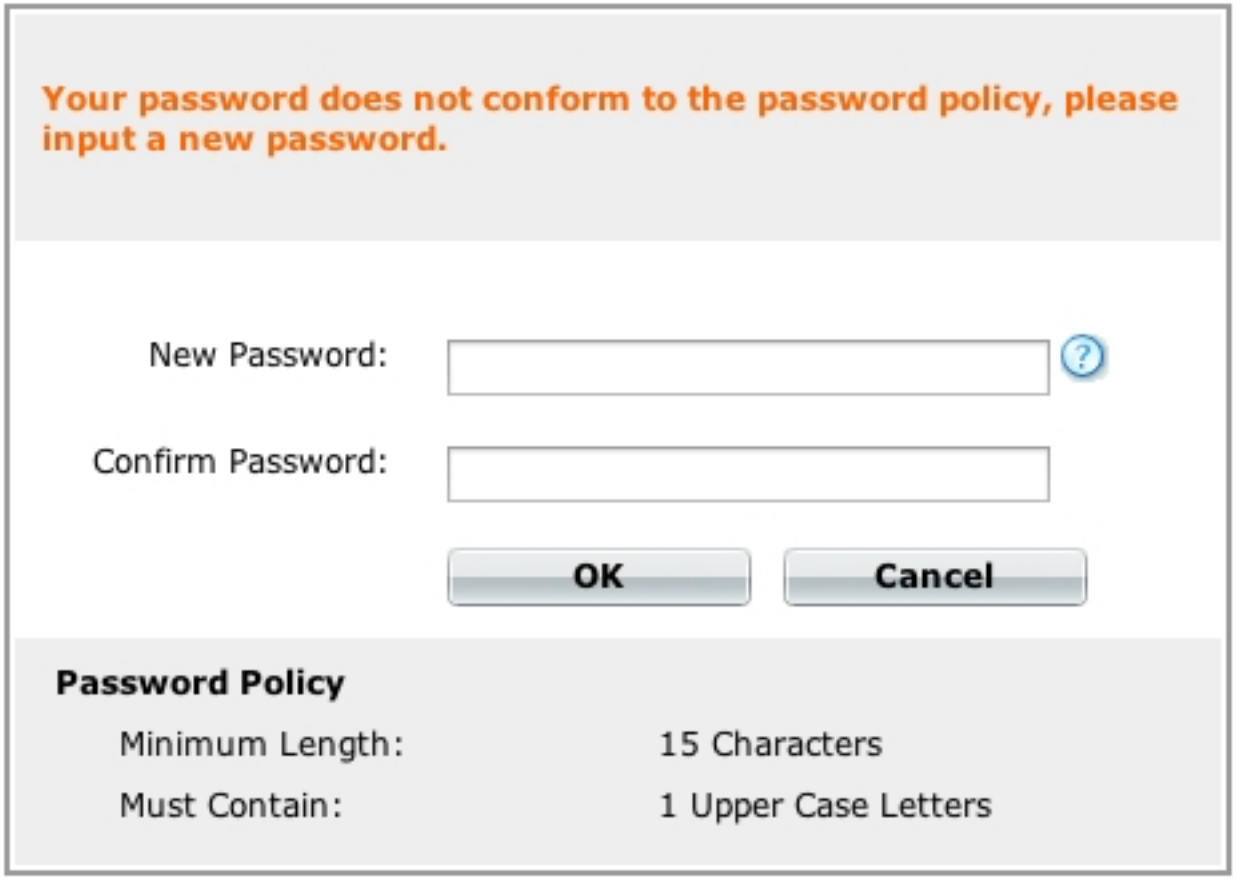
To apply a password policy - CLI

```
config system password-policy
   set status enable
```

Configure the other settings as required.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate unit, they are prompted to update their password to meet the new requirements before proceeding to log in.

Password policy dialog box



Lost Passwords

If an administrator password has been lost, refer to the SysAdmin's Notebook article "Resetting a lost admin password," found at docs.fortinet.com/p/sysadmin-s-notebook-and-tech-notes.

Configuration Backups

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it. You should also backup the local certificates, as the unique SSL inspection CA and server certificates that are generated by your FortiGate by default are not saved in a system backup.

It is also recommended that once *any* further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site. The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

Backing up the configuration using the web-based manager

1. Go to **System > Dashboard > Status**.
2. On the **System Information** widget, select **Backup** for the **System Configuration**.
3. Select to backup to your **Local PC** or to a **USB key**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.
   Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

Backing up the configuration using the CLI

Use the following command:

```
execute backup config management-station <comment>
```

… or …

```
execute backup config usb <backup_filename> [<backup_password>]
```

… or for FTP, note that port number, username are optional depending on the FTP site…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
    [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
   edit <vdom_name>
```

Backup and restore the local certificates

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

Backing up the local certificates

Connect to the CLI and use the following command:

```
execute vpn certificate local export tftp <cert_name> <filename> <tftp_ip>
```

where:

- `<cert_name>` is the name of the server certificate.
- `<filename>` is a name for the output file.
- `<tftp_ip>` is the IP address assigned to the TFTP server host interface.

Restoring the local certificates - web-based manager

1. Move the output file from the TFTP server location to the management computer.
2. Go to **System > Certificates > Local Certificates** and select **Import**.
3. Select the appropriate **Type** of certificate and fill in any required fields.
4. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file and select **Open**.
5. If required, enter the **Password** needed to upload the exported file..
6. Select **OK**.

Restoring the local certificates - CLI

Connect to the CLI and use the following command:

```
execute vpn certificate local import tftp <filename> <tftp_ip>
```

Backup and restore a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for and administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global
   set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
   set admin-scp enable
end
config vdom
   edit <vdom_name>
```

Enable SSH access on the interface

SCP uses the SSH protocol to provide secure file transfer. The interface you use for administration must allow SSH access.

To enable SSH - web-based manager:

1. Go to **System > Network > Interface**.
2. Select the interface you use for administrative access and select **Edit**.
3. In the **Administrative Access** section, select **SSH**.
4. Select **OK**.

To enable SSH - CLI:

```
config system interface
   edit <interface_name>
      set allowaccess ping https ssh
end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

...only PING will be set. In this case, you must type...

```
set allowaccess https ssh ping
```

Using the SCP client

The FortiGate unit downloads the configuration file as `sys_conf`. Use the following syntax to download the file:

Linux

```
scp admin@<FortiGate_IP>:fgt-config <location>
```

Windows

```
pscp admin@<FortiGate_IP>:fgt-config <location>
```

The following examples show how to download the configuration file from a FortiGate-100D, at IP address 172.20.120.171, using Linux and Windows SCP clients.

Linux client example

To download the configuration file to a local directory called `~/config`, enter the following command:

```
scp admin@172.20.120.171:fgt-config ~/config
```

Enter the admin password when prompted.

Windows client example

To download the configuration file to a local directory called c:\config, enter the following command in a Command Prompt window:

```
pscp admin@172.20.120.171:fgt-config c:\config
```

Enter the admin password when prompted.

SCP public-private key authentication

SCP authenticates itself to the FortiGate unit in the same way as an administrator using SSH accesses the CLI. Instead of using a password, you can configure the SCP client and the FortiGate unit with a public-private key pair.

To configure public-private key authentication

1. Create a public-private key pair using a key generator compatible with your SCP client.
2. Save the private key to the location on your computer where your SSH keys are stored.
   This step depends on your SCP client. The Secure Shell key generator automatically stores the private key.
3. Copy the public key to the FortiGate unit using the CLI commands:

```
config system admin
   edit admin
      set ssh-public-key1 "<key-type> <key-value>"
   end
```

   `<key-type>` must be the ssh-dss for a DSA key or ssh-rsa for an RSA key. For the `<key-value>`, copy the public key data and paste it into the CLI command.

   If you are copying the key data from Windows Notepad, copy one line at a time and ensure that you paste each line of key data at the end of the previously pasted data. As well:

   - Do not copy the end-of-line characters that appear as small rectangles in Notepad.
   - Do not copy the `---- BEGIN SSH2 PUBLIC KEY ---- or Comment: "[2048-bit dsa,...]"` lines.
   - Do not copy the `---- END SSH2 PUBLIC KEY ----` line.
4. Type the closing quotation mark and press **Enter**.

Your SCP client can now authenticate to the FortiGate unit based on SSH keys rather than the administrator password.

Restoring a configuration using SCP

To restore the configuration using SCP, use the commands:

```
scp <local_file> <admin_user>@<FGT_IP>:fgt-restore-config
```

To use this command/method of restoring the FortiGate configuration, you need to log in as the “admin” administrator.

Restoring a configuration

Should you need to restore a configuration file, use the following steps:

To restore the FortiGate configuration - web-based manager

1. Go to **System > Dashboard > Status**.
2. On the **System Information** widget, select **Restore** for the **System Configuration**.

3. Select to upload the configuration file to be restored from your **Local PC or a USB key**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
4. Enter the path and file name of the configuration file, or select **Browse** to locate the file.
5. Enter a password if required.
6. Select **Restore**.

To back up the FortiGate configuration - CLI

```
execute restore config management-station normal 0
```

… or …

```
execute restore config usb <filename> [<password>]
```

… or for FTP, note that port number, username are optional depending on the FTP site…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_
    name>] [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_server> <password>
```

The FortiGate unit will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

Configuration revisions

The **Revisions** options on the **System Information** widget enables you to manage multiple versions of configuration files. Revision control requires either a configured central management server, or FortiGate units with 512 MB or more of memory. The central management server can either be a FortiManager unit or the FortiCloud.

When revision control is enabled on your unit, and configurations have been backed up, a list of saved revisions of those backed-up configurations appears.

Restore factory defaults

There may be a point where need to reset the FortiGate unit to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration:

To reset the FortiGate unit to its factory default settings - web-based manager

1. Go to **System > Dashboard > Status**.
2. In the **System Information** widget, select **Restore** for the **System Configuration**.
3. Select **Restore Factory Defaults** at the top of the page.

You can reset using the CLI by entering the command:

```
execute factoryreset
```

When prompted, type `y` to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration.

Use the command:

```
execute factoryreset2
```

Next Steps

Now that you have installed and set up your FortiGate unit, here's a list of some resources you can read next to help you continue to get the most out of your FortiGate.

Best Practices

The Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGate units in a customer environment. It is updated periodically as new issues are identified.

This document can be found at http://docs.fortinet.com/d/fortigate-best-practices.

The FortiGate Cookbook

The FortiGate Cookbook contains a variety of step-by-step examples of how to integrate a FortiGate unit into your network and apply features such as security profiles, wireless networking, and VPN.

Using the Cookbook, you can go from idea to execution in simple steps, configuring a secure network for better productivity with reduced risk.

The FortiGate Cookbook can be found at http://cookbook.fortinet.com.

The Fortinet Video Library

The Fortinet Video Library contains video tutorials showing how to configure various Fortinet products, including FortiGate units. Many FortiGate videos are based on recipes from the FortiGate Cookbook.

The Fortinet Video Library can be found at http://video.fortinet.com.

The FortiOS Handbook

The FortiOS Handbook is the complete guide to FortiOS, covering a variety of FortiGate configurations.

The FortiOS Handbook is available as a single, complete document. Handbook chapters are also available as standalone documents.

The FortiOS Handbook can be found at http://docs.fortinet.com/fortigate/admin-guides.

Chapter 3 - Advanced Routing

This chapter describes advanced static routing concepts and how to implement dynamic routing on FortiGate units.

This FortiOS Handbook chapter contains the following sections:

Advanced Static Routing explains universal and static routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

Dynamic Routing Overview provides an overview of dynamic routing, compares static and dynamic routing, and helps you decide which dynamic routing protocol is best for you.

Routing Information Protocol (RIP) describes a distance-vector routing protocol intended for small, relatively homogeneous networks.

Border Gateway Protocol (BGP) describes classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol.

Open Shortest Path First (OSPF) provides background on the specific protocol explaining terms used and how the protocol works, as well as providing some troubleshooting information and examples on configuring the protocols in different situations.

Intermediate System to Intermediate System Protocol(IS-IS), which describes the link state protocol, is well-suited to smaller networks and with near universal support on routing hardware. The section also provides troubleshooting information and configuration examples.

Advanced Static Routing

Advanced static routing includes features and concepts that are used in more complex networks. Dynamic routing is not addressed in this section.

This section includes:

Routing concepts
Static routing tips
Policy routing
Transparent mode static routing
Static routing example
Advanced static routing example: ECMP failover and load balancing

Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

This section includes:

- Routing in VDOMs
- Default route
- Adding a static route
- Routing table
- Building the routing table
- Static routing security
- Multipath routing and determining the best route
- Route priority
- Troubleshooting static routing

Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled you will need to perform the following steps in addition to the procedure's steps.

To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
   edit root
```

Following these commands, you can enter any routing CLI commands as normal.

Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address.

Adding a static route

To add or edit a static route, go to **Router > Static > Static Routes** and select **Create New**.

Destination IP / Mask	Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` is universal.
Device	Select the name of the interface which the static route will connect through.
Gateway	Enter the gateway IP address.
Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Priority	Enter the priority if desired, which will artificially weight the route during route selection. The higher the number, the less likely the route is to be selected over others. The default is 0.

Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address - you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people in that the routing table maintains a list of

how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers loose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes such as these happen along a static route, traffic can no longer reach the destination — the route goes down. Dynamic routing can address these changes to ensure traffic still reaches its destination. The process of realizing there is a problem, backtracking and finding a route that is operational is called convergence. If there is fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes—the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes — the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Some actions you can perform on the routing table include:

- Viewing the routing table in the web-based manager
- Viewing the routing table in the CLI
- Searching the routing table

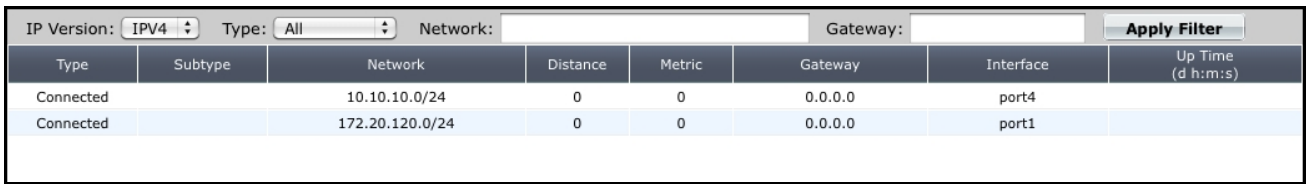
Viewing the routing table in the web-based manager

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to **Router > Monitor > Routing Monitor**.

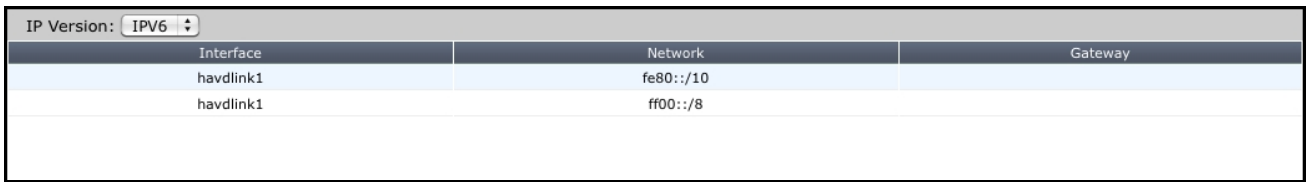
The figure below shows the Routing Monitor list belonging to a FortiGate unit that has interfaces named "port1", "port4", and "lan". The names of the interfaces on your FortiGate unit may be different.

Routing Monitor list - IPv4



The following figure shows the Routing Monitor list when IPv6 has been selected. Note that the information available for IPv6 is limited.

Routing Monitor list - IPv6



IP Version	Select IPv4 or IPv6. This is available only when IPv6 is enabled in the web-based manager. The fields displayed in the table depend on which IP version is selected.
Type	The type values assigned to FortiGate unit routes (Static, Connected, RIP, OSPF, or BGP). **All** — all routes recorded in the routing table. **Connected** — all routes associated with direct connections to FortiGate unit interfaces. **Static** — the static routes that have been added to the routing table manually. **RIP** — all routes learned through RIP. For more information see Routing Information Protocol (RIP) on page 295. **RIPNG** — all routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks). **BGP** — all routes learned through BGP. For more information see Border Gateway Protocol (BGP) on page 332. **OSPF** — all routes learned through OSPF. For more information see Open Shortest Path First (OSPF) on page 371. **OSPF6** — all routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks). **IS-IS** — all routes learned through IS-IS. For more information see Intermediate System to Intermediate System Protocol(IS-IS) on page 412. **HA** — RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IP version IPv6 is selected. For details about HA routing synchronization, see the FortiGate HA User Guide.

Subtype	If applicable, the subtype classification assigned to OSPF routes. An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected. **OSPF inter area** — the destination is in the OSPF AS, but the FortiGate unit is not connected to that area. **External 1** — the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. **External 2** — the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. **OSPF NSSA 1** — same as External 1, but the route was received through a not-so-stubby area (NSSA). **OSPF NSSA 2** — same as External 2, but the route was received through a not-so-stubby area. For more information on OSPF subtypes, see Open Shortest Path First (OSPF) on page 371. Not displayed when IP version 6 is selected.
Network	The IP addresses and network masks of destination networks that the FortiGate unit can reach.
Gateway	The IP addresses of gateways to the destination networks.
Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. Not displayed when IP version IPv6 is selected.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate unit may routinely use the route to communicate with neighboring routers and access servers. Modifying this distance for dynamic routes is route distribution. See Border Gateway Protocol (BGP) on page 332. Not displayed when IP version 6 is selected.

Metric	The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. **Hop count** — routes learned through RIP. **Relative cost** — routes learned through OSPF. **Multi-Exit Discriminator (MED)** — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see Border Gateway Protocol (BGP) on page 332. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column will display a non-zero value. Not displayed when IP version 6 is selected.

Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get route static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O  - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i  - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
*  - candidate default

S*  0.0.0.0/0 [10/0] via 192.168.183.254, port2
S    1.0.0.0/8 [10/0] via 192.168.183.254, port2
S   2.0.0.0/8 [10/0] via 192.168.183.254, port2
C   10.142.0.0/23 is directly connected, port3
B   10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

To view the kernel routing table

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->10.11.201.0/24
    pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->172.20.120.0/24
    pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

tab	Table number. This will be either 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.
type	Type of routing connection. Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited
proto	Type of installation. This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->10.11.201.0/24 **(->x.x.x.x/mask)**	The IP address and subnet mask of the destination
pref	Preferred next hop along this route
gwy	Gateway - the address of the gateway this route will use
dev	Outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface it will also be displayed here.

Searching the routing table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table

entry in order for that entry to be displayed — an implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select **Connected** from the **Type** list, type `172.16.14.0/24` in the **Network** field, and then select **Apply Filter** to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its **Type** field and the specified value in the **Gateway** field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24

To search the FortiGate unit routing table in the web-based manager

1. Go to **Router > Monitor > Routing Monitor**.
2. From the **Type** list, select the type of route to display. In our example, select **Static**.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the Networks field. In our example, enter `10.10.10.10/24`.
4. If you want to display routes to a specific gateway, type the IP address of the gateway in the **Gateway** field.
5. Select **Apply Filter**.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the FortiGate unit routing table in the CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
   Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed, with the best match at the top of the list as indicated by the word best.

Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination—the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit’s forwarding table, which is a subset of the unit’s routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers not only can steal your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

This section includes:

- Network Address Translation (NAT)
- Access Control List (ACL)
- Blackhole Route
- Reverse path lookup

Network Address Translation (NAT)

Network address translation (NAT) is a method of changing the address from which traffic appears to originate. This practice is used to hide the IP address on a company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network as would be the case without NAT. Securing one computer is much cheaper and easier to maintain.

1. Configuring NAT on your FortiGate unit includes the following steps.
2. Configure your internal network. For example use the `10.11.101.0` subnet.
3. Connect your internal subnet to an interface on your FortiGate unit. For example use `port1`.
4. Connect your external connection, for example an ISP gateway of `172.20.120.2`, to another interface on your Fortigate unit, for example `port2`.

Configure security policies to allow traffic between port1 and port2 on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the 10.11.101.0 subnet and pass on to the 172.20.120.0 network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet — it does not appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the Fortigate unit, but will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider only can access the FortiGate unit's external interface unless the security policy allows the traffic through to the internal network. If allowed in, the proper internal user would respond to the chat. However if its not allowed, the request to chat will be refused or time-out. This is accomplished in the security policy by allowing or denying different protocols.

Access Control List (ACL)

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router looks up in the ACL if that traffic is allowed over that port or not. If it is allowed on that incoming interface, then the next step is to check the ACL for the destination interface. If the traffic passes that check as well the buffered traffic is delivered to its accentuation. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths, and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective the ACL must be kept up to date —when employees or computers are removed from the internal network their IP addresses must also be removed from the ACL. For more information on the ACL, see the router chapter of the FortiGate CLI Reference.

Blackhole Route

A blackhole route is a route that drops all traffic sent to it. It is very much like /dev/null in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses (traffic which may be valid or malicious) can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, a virtual interface that does not forward traffic, was added to enable easier configuration of blackhole routing. Similar to a normal interface, this loopback interface has fewer parameters to configure, and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the FortiGate CLI Reference.

Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address (and the local configuration permits delivery), the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the Fortigate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works — if there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available), the traffic will use the route with an administrative distance of 5. If for some reasons the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. The default administrative distances for any of these routing protocols are configurable.

Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110
IS-IS	115
RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route be set in the CLI, or when editing a specific static route, as

described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes having the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols such as RIP can use metrics that are similar to administrative distance.

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

To change the priority of a route - web-based manager

1. Go to **Router > Static > Static Routes**.
2. Select the route entry, and select **Edit**.
3. Select **Advanced**.
4. Enter the **Priority** value.
5. Select **OK**.

To change the priority of a route - CLI

The following command changes the priority to 5 for a route to the address `10.10.10.1` on the `port1` interface.

```
config router static
   edit 1
      set device port1
      set gateway 10.10.10.10
      set dst 10.10.10.1
      set priority 5
   end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Troubleshooting static routing

When there are problems with your network that you believe to be static routing related, there are a few basic tools available to locate the problem.

These tools include:

- Ping
- Traceroute
- Examine routing table contents

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- Possible ECMP, split horizon, network loops
- Cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- Hardware - ensure cabling is correct, and all equipment between the two locations is accounted for
- Addresses and routes - ensure all IP addresses and routing information along the route is configured as expected
- Firewalls - ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

To ping from an Apple computer

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

To ping from a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/ping 10.11.101.101`".

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

To use traceroute on an Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter "`cmd`" and select **OK**.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet website.

To use traceroute from an Apple computer

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

To use traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/traceroute fortinet.com`".
   The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor — go to **Router > Monitor > Routing Monitor**. In the CLI, use the command `get router info routing-table all`.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing configured on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few

addresses as gateways, if there is an outage on the network it will either be very localized or network-wide — either is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially is puts all your resources on the network, and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks, and helping troubleshoot any routing problems that come up. Also you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing, and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step.
- Implement black hole routing to hide which IP addresses are in use or not on your local network.
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network.

All three features limit access to the people who should be using your network, and obscure your network information from the outside world and potential hackers.

Policy routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional,and a matching policy alone might not provide enough information for forwarding the packet. In fact, the FortiGate almost always requires a matching route in the routing table in order to use a policy route. The FortiGate unit will refer to the routing table in an attempt to match the information in the packet header with a route in the routing table.

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to **Router > Static > Policy Routes**.

Create New	Add a policy route. See Adding a policy route on page 259.
Edit	Edit the selected policy route.
Delete	Delete the selected policy route.
Move To	Move the selected policy route. Enter the new position and select **OK**. For more information, see Moving a policy route on page 262.
#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to **Router > Static > Policy Route** and select **Create New**.

Protocol	Enter the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of `0` disables the feature. Commonly used **Protocol** settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see Type of Service on page 261.
Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic set protocol to 6 (for TCP) and set both of the destination ports to 21, the FTP port.

Protocol	6
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Type of Service

Type of service (TOS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see RFC 791 and RFC 1349.

The role of each bit in the IP header TOS 8-bit field

bits 0, 1, 2	**Precedence**	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits.
bit 3	**Delay**	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.
bit 4	**Throughput**	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth such as video conferencing.
bit 5	**Reliability**	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available such as with DNS servers.
bit 6	**Cost**	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3,4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	**Reserved for future use**	Not used at this time.

For example, if you want to assign low delay, and high reliability, say for a VoIP application where delays are unacceptable, you would use a bit pattern of xxx1x1xx where an 'x' indicates that bit can be any value. Since all bits are not set, this is a good use for the bit mask; if the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example `172.20.0.0/255.255.0.0` and `172.20.120.0/255.255.255.0`. If both of these routes are in the policy table, both can match a route to `172.20.120.112` but you consider the second one as a better match. In that case the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to **Router > Static > Policy Routes** and select **Move To** for the policy route you want to move.

Before/After	Select Before to place the selected Policy Route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.

Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT/Route operating mode is the standard mode where all interfaces are accessed individually, and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge — traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT/Route mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to **System > Network > Routing Table**.

When viewing or creating a static route entry in transparent mode there are only three fields available.

Destination IP / Mask	The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed. Use 0.0.0.0 to match all traffic destinations. This is the default route.
Gateway	Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.
Priority	The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable the other routes can be used instead. Valid range of priority can be from 0 to 4 294 967 295. If more than one route matches and they have the same priority it becomes an ECMP situation and traffic is shared among those routes. See Transparent mode static routing on page 262.

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet then all static routing on the FortiGate unit will use that gateway. For this reason static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT/Route mode.

Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dentist office that includes a number of dentists, assistants, and office staff. The size of the office is not expected to grow significantly in the near future, and the network usage is very stable—there are no new applications being added to the network.

The users on the network are:

- Admin staff - access to local patient records, and perform online billing
- Dentists - access and update local patient records, research online from desk
- Assistants - access and update local patient records in exam rooms

The distinction here is mainly that only the admin staff and dentist's office need access to the Internet—all the other traffic is local and doesn't need to leave the local network. Routing is only required for the outbound traffic, and the computers that have valid outbound traffic.

Configuring routing only on computers that need it acts as an additional layer of security by helping prevent malicious traffic from leaving the network.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configure FortiGate unit
- Configure Admin PC and Dentist PCs
- Testing network configuration

Network layout and assumptions

The computers on the network are admin staff computers, dentist office computers, and dental exam room computers. While there are other devices on the local network such as printers, they do not need Internet access or any routing.

This networked office equipment includes 1 admin staff PC, 3 dentist PCs, and 5 exam room PCs. There are also a network printer, and a router on the network as well.

Assumptions about these computers, and network include:

- The FortiGate unit is a model with interfaces labeled port1 and port2.
- The FortiGate unit has been installed and is configured in NAT/Route mode.
- VDOMs are not enabled.
- The computers on the network are running MS Windows software.
- Any hubs required in the network are not shown in the network diagram.
- The network administrator has access to the ISP IP addresses, and is the super_admin administrator on the FortiGate unit.

Static routing example device names, IP addresses, and level of access

Device Name(s)	IP address	Need external access?
Router	192.168.10.1	YES
Admin	192.168.10.11	YES
Dentist1-3	192.168.10.21-23	YES
Exam1-5	192.168.10.31-35	NO
Printer	192.168.10.41	NO

General configuration steps

The steps to configuring routing on this network are:

1. Get your ISP information such as DNS, gateway, etc.
2. Configure FortiGate unit
3. Configure Admin PC and Dentist PCs
4. Testing network configuration

Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses needed for routing are your assigned IP address, DNS servers, and the gateway.

Configure FortiGate unit

The FortiGate unit will have two interfaces in use—one connected to the internal network and one connected to the external network. Port1 will be the internal interface, and port2 will be the external interface.

To configure the FortiGate unit:

1. Configure the internal interface (port1)
2. Configure the external interface (port2)
3. Configure networking information
4. Configure basic security policies
5. Configure static routing

Configure the internal interface (port1)

To configure the internal interface (port1) - web based manager

1. Go to **System > Network > Interfaces**. Highlight **port1** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port1) - CLI

```
config system interface
   edit port1
      set IP 192.168.10.1 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure the external interface (port2)

The external interface connects to your ISP's network. You need to know the IP addresses in their network that you should connect to. Use their addresses when you get them, however for this example we will assume the address your ISP gave you is 172.100.20.20 will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

To configure the internal interface (port2) - web based manager

1. Go to **System > Network > Interfaces**. Highlight **port2** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.20.20/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port2) - CLI

```
configure system interface
   edit port2
      set IP 172.100.20.20 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure networking information

Networking information includes the gateway, and DNS servers. Your FortiGate unit requires a connection to the Internet for antivirus and other periodic updates.

To configure networking information - web-based manager

1. Go to **System > Network > DNS**.
2. Enter the primary and secondary DNS addresses.
3. Select **Apply**.

To configure networking information - CLI

```
config system global
   set dns_1 172.11.22.33
   set dns_2 172.11.22.34
end
```

Configure basic security policies

For traffic to flow between the internal and external ports in both directions, two security policies are required as a minimum. More can be used to farther limit or direct traffic as needed, but will not be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- Only the basic networking services have been listed as allowed for added security. Others can easily be added as the users require them.

- In this example to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users to update their software. The FortiGate unit can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

To configure security policies - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create a new Firewall Address entry for each of:

PC Name	IP Address	Interface
Admin	192.168.10.11	port1
Dentist1	192.168.10.21	port1
Dentist2	192.168.10.22	port1
Dentist3	192.168.10.23	port1

3. Go to **Policy & Objects > Objects > Addresses**.
4. Select the dropdown arrow next to **Create New** and select **Address Group**.
5. Name the group Internet_PCs.
6. Add Admin, Dentist1, Dentist2, and Dentist3 as members of the group.
7. Select **OK**.
8. Go to **Policy & Objects > Policy > IPv4**.
9. Select **Create New**.
10. Enter the following: DH - port2(external) -> port1(internal)

Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Internet_PCs
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

11. Select **OK**.
12. Select **Create New**.

13. Enter the following:

Incoming Interface	port1
Source Address	Internet_PCs
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

14. Select **OK**.

To configure security policies - CLI

```
config firewall address
   edit "Admin"
      set associated-interface "port1"
      set subnet 192.168.10.11 255.255.255.255
   next
   edit "Dentist1"
      set associated-interface "port1"
      set subnet 192.168.10.21 255.255.255.255
   next
   edit "Dentist2"
      set associated-interface "port1"
      set subnet 192.168.10.22 255.255.255.255
   next
   edit "Dentist3"
      set associated-interface "port1"
      set subnet 192.168.10.23 255.255.255.255
   end
config firewall addrgrp
   edit Internet_PCs
      set member Admin Dentist1 Dentist2 Dentist3
   end
config firewall policy
   edit 1
      set srcintf port1
      set dstintf port2
      set srcaddr Internet_PCs
      set dstaddr all
      set action accept
      set schedule always
      set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
      set logtraffic enable
      set label "Section2"
```

```
        set endpoint-restrict-check no-av db-outdated
      next
      edit 2
        set srcintf port2
        set dstintf port1
        set srcaddr all
        set dstaddr Internet_PCs
        set action accept
        set schedule always
        set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
        set logtraffic enable
        set label "Section2"
        set endpoint-restrict-check no-av db-outdated
      end
    end
```

Configure static routing

With the rest of the FortiGate unit configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

To configure Fortinet unit static routing - web-based manager

1. Go to **Router > Static > Static Routes**.
2. Select **Edit** for the top route on the page.
3. Enter the following:

Destination IP/Mask	172.100.20.5
Device	port2
Gateway	172.100.20.5
Distance	10

4. Select **OK**.

To configure Fortinet unit static routing - CLI

```
config router static
  edit 1
    set gateway 172.100.20.5
    set distance 10
    set device port2
    set dst 0.0.0.0
  end
end
```

Configure Admin PC and Dentist PCs

With the router configured, next we need to configure the computers that need Internet access. These computers need routing to be configured on them. As the other computers do not require routing, they are not included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure does not configure the DNS entries. It just adds the static routes.

To configure routing and DNS on Admin and Dentist PCs - Windows GUI

1. On PC, select **Start > Control Panel > Network Connections**.
2. Right click on the network connection to your local network that has a status of Connected, and select **Properties**.
3. Under the **General** tab, from the list select **TCP/IP**, and **Properties**.
4. Under **Gateway**, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select **OK**.

To configure routing on Admin and Dentist PCs - Windows CLI

1. On PC, select **Start > Run**, enter "`cmd`", and select **OK**.
2. At the command prompt, type
   ```
   route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
   route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
   ```
3. Confirm these routes have been added. Type:
   ```
   route PRINT
   ```
   If you do not see the two routes you added, try adding them again paying attention to avoid spelling mistakes.
4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate unit.

Configure other PCs on the local network

The PCs on the local network without Internet access (the exam room PCs) can be configured now.

As this step does not require any routing, details have not been included.

Testing network configuration

There are three tests to run on the network to ensure proper connectivity.

- To test that PCs on the local network can communicate
- Test that Internet_PCs on the local network can access the Internet
- Test that non-Internet_PCs can not access the Internet

Test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt enter `ping 192.168.10.23.`
   The output from this command should appear similar to the following.

```
Pinging 192.168.10.23 with 32 bytes of data:

Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt enter `ping 192.168.10.34.`
   The output from this command should appear similar to the following.

```
Pinging 192.168.10.34 with 32 bytes of data:

Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.
   If the output does not appear similar to above, there is a problem with the network configuration between these two PCs.

To test that Internet_PCs on the local network can access the Internet

The easiest way to access the Internet is with an Internet browser. However, if that doesn't work its best to do a traceroute to see at what point the problem is. This can help determine if it is a networking problem such as cabling, or if its an access problem such as this PC not having Internet access.

1. Select any PC on the local network that is supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet such as http://www.fortinet.com.
   If this is successful, this PC has Internet access.
3. If step2 was not successful, at the command prompt on the PC enter `traceroute 22.11.22.33.`
   The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:

Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

Advanced static routing example: ECMP failover and load balancing

Equal Cost Multi-Path (ECMP) load balancing and failover are methods that extend basic static routing. They allow you to use your network bandwidth more effectively and with less down time than if you used basic static routing alone.

The concepts in this section include:

- Equal-Cost Multi-Path (ECMP)
- Configuring interface status detection for gateway load balancing
- Configuring spillover or usage-based ECMP
- Configuring weighted static route load balancing

Equal-Cost Multi-Path (ECMP)

FortiOS uses equal-cost multi-path (ECMP) to distribute traffic to the same destination such as the Internet or another network. Using ECMP you can add multiple routes to the destination and give each of those routes the same distance and priority.

If multiple routes to the same destination have the same priority but different distances, the route with the lowest distance is used. If multiple routes to the same destination have the same distance but different priorities, the route with the lowest priority is used. Distance takes precedence over priority. If multiple routes to the same destination have different distances and different priorities, the route with the lowest distance is always used even if it has the highest priority.

If more than one ECMP route is available, you can configure how the FortiGate unit selects the route to be used for a communication session. If only one ECMP route is available (for example, because an interface cannot process traffic because interface status detection does not receive a reply from the configured server) then all traffic uses this route.

Previous versions of FortiOS provided source IP-based load balancing for ECMP routes, but now FortiOS includes three configuration options for ECMP route failover and load balancing:

Source IP based (also called source IP based)	The FortiGate unit load balances sessions among ECMP routes based on the source IP address of the sessions to be load balanced. This is the default load balancing method. No configuration changes are required to support source IP load balancing.
Weighted Load Balance (also called weight-based)	The FortiGate unit load balances sessions among ECMP routes based on weights added to ECMP routes. More traffic is directed to routes with higher weights. After selecting weight-based you must add weights to static routes.
Spillover (also called usage-based)	The FortiGate unit distributes sessions among ECMP routes based on how busy the FortiGate interfaces added to the routes are. After selecting spill-over you add route Spillover Thresholds to interfaces added to ECMP routes. The FortiGate unit sends all ECMP-routed sessions to the lowest numbered interface until the bandwidth being processed by this interface reaches its spillover threshold. The FortiGate unit then spills additional sessions over to the next lowest numbered interface. The Spillover Thresholds range is 0-2097000 KBps.
Source-Destination IP based	The FortiGate unit load balances sessions among ECMP routes based on both the source and destination IP addresses of the sessions to be load balanced. This is required particularly for L3 link aggregation hashing.

You can configure only one of these ECMP route failover and load balancing methods in a single VDOM. If your FortiGate unit is configured for multiple VDOM operation, each VDOM can have its own ECMP route failover and load balancing configuration.

To configure the ECMP load balancing method from the web-based manager

1. Go to **Router > Static > Settings**.
2. Set **ECMP Load Balancing Method** to **Source IP based**, **Weighted Load Balance**, or **Spillover.**

To configure the ECMP load balancing method from the CLI

For example, to set the load balancing method to usage-based, enter the following:

```
config system settings
   set v4-ecmp-mode usage-based
end
```

ECMP routing of simultaneous sessions to the same destination IP address

When the FortiGate unit selects an ECMP route for a session, a route cache is created that matches the route with the destination IP address of the session. All new sessions to the same destination IP address from the same source IP address use the same route until the route is flushed from the cache. Routes are flushed from the cache after a period of time when no new sessions to the destination IP address are received.

The route cache improves FortiGate unit routing performance by reducing how often the FortiGate unit looks up routes in the routing table.

If the FortiGate unit receives a large number of sessions with the same destination IP address, because all of these sessions will be processed by the same route, it may appear that sessions are not distributed according to the ECMP route failover and load balancing configuration.

Configuring interface status detection for gateway load balancing

Interface status detection is used for ECMP route failover and load balancing. Interface status detection consists of the unit confirming that packets sent from an interface result in a response from a server. You can use up to three different protocols to confirm that an interface can connect to the server. Usually the server is the next-hop router that leads to an external network or the Internet. Interface status detection sends a packet using the configured protocols. If a response is received from the server, the unit assumes the interface can connect to the network. If a response is not received, the unit assumes that the interface cannot connect to the network.

Since it is possible that a response may not be received, even if the server and the network are operating normally, the dead gateway detection configuration controls the time interval between testing the connection to the server and the number of times the test can fail before the unit assumes that the interface cannot connect to the server.

As long as the unit receives responses for at least one of the protocols that you select, the unit assumes the server is operating and can forward packets. Responding to more than one protocol does not enhance the status of the server or interface.

To configure gateway failover detection for an interface - web-based manager

1. Go to **Router > Static > Settings**.
2. Under **Link Health Monitor**, select **Create New**.
3. Enter the following information:

Name	Give the monitor a name
Interface	Select the interface to test.
Gateway	Enter the IP address of the gateway.
Probe Type	Select the method of probe type, either Ping or HTTP.
Server	Address of Server to test. The address can be an IP address or FQDN. In some builds of the firmware if an invalid address is entered an error message comes up stating “Please enter an IP, IP range, FQDN, or comma separated list of IPs and/or FQDNs.” This is incorrect. Ranges cannot be used.
Probe Interval(s)	Enter the interval between pings, in seconds.
Failure Threshold	Enter the number of times the test can fail before the unit assumes that the interface cannot connect to the server.
Recovery Threshold	Configure the threshold for ECMP recovery, ranging from 1 to 10.
HA Priority	Set the HA priority, if configuring an HA cluster.

4. Select **OK**.

To configure gateway failover detection for an interface - CLI

```
config system link-monitor
   edit "test"
      set srcintf "internal4"
      set server "8.8.8.8"
      set update-cascade-interface disable
   end
```

Configuring spillover or usage-based ECMP

Spill-over or usage-based ECMP routes new sessions to interfaces that have not reached a configured bandwidth limit (called the **Spillover Threshold** or a route-spillover threshold). To configure spill-over or usage-based ECMP routing, you enable spill-over ECMP, add ECMP routes, and add a **Spillover Threshold** to the interfaces used by the ECMP routes. Set the **Spillover Thresholds** to limit the amount of bandwidth processed by each interface. The range is 0 to 2 097 000 Kbps. The threshold counts only outgoing traffic.

With spill-over ECMP routing configured, the FortiGate unit routes new sessions to an interface used by an ECMP route until that interface reaches its **Spillover Threshold**. Then, when the threshold of that interface is reached, new sessions are routed to one of the other interfaces used by the ECMP routes.

To add Spillover Thresholds to interfaces - web-based manager

Use the following steps to enable usage based ECMP routing, add Spillover Thresholds to FortiGate interfaces port3 and port4, and then to configure EMCP routes with device set to port3 and port4.

1. Go to **Router > Static > Settings**.
2. Set **ECMP Load Balance Method** to **Spillover**.

3. Go to **Router > Static > Static Route**s.
4. Add ECMP routes for `port3` and `port4`.

Destination IP/Mask	192.168.20.0/24
Device	port3
Gateway	172.20.130.3
Advanced	
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port4
Gateway	172.20.140.4
Advanced	
Distance	10

5. Go to **System > Network > Interfaces**.
6. Edit `port3` and `port4` and add the following spillover-thresholds:

Interface	port3
Spillover Threshold	100

Interface	port4
Spillover Threshold	200

To add Spillover Thresholds to interfaces - CLI

```
config system settings
   set v4-ecmp-mode usage-based
end
config router static
   edit 1
      set device port3
      set dst 192.168.20.0 255.255.255.0
      set gateway 172.20.130.3
   next
   edit 2
      set device port4
      set dst 192.168.20.0 255.255.255.0
      set gateway 172.20.140.4
   end
config system interface
```

```
edit port3
   set spillover-threshold 100
next
edit port4
   set spillover-threshold 200
end
```

Detailed description of how spill-over ECMP selects routes

When you add ECMP routes they are added to the routing table in the order displayed by the routing monitor or by the `get router info routing-table static` command. This order is independent of the configured bandwidth limit.

The FortiGate unit selects an ECMP route for a new session by finding the first route in the routing table that sends the session out a FortiGate unit interface that is not processing more traffic that its configured route spill-over limit.

A new session to a destination IP address that already has an entry in the routing cache is routed using the route already added to the cache for that destination address. See ECMP routing of simultaneous sessions to the same destination IP address on page 273.

For example, consider a FortiGate unit with interfaces port3 and port4 both connected to the Internet through different ISPs. ECMP routing is set to usage-based and route spillover for to 100 Kbps for port3 and 200 Kbps for port4. Two ECMP default routes are added, one for port3 and one for port4.

If the route to port3 is higher in the routing table than the route to port4, the FortiGate unit sends all default route sessions out port3 until port3 is processing 100Kbps of data. When port3 reaches its configured bandwidth limit, the FortiGate unit sends all default route sessions out port4. When the bandwidth usage of port3 falls below 100Kbps, the FortiGate again sends all default route sessions out port3.

New sessions with destination IP addresses that are already in the routing cache; however, use the cached routes. This means that even if port3 is exceeding its bandwidth limit, new sessions can continue to be sent out port3 if their destination addresses are already in the routing cache. As a result, new sessions are sent out port4 only if port3 exceeds its bandwidth limit and if the routing cache does not contain a route for the destination IP address of the new session.

Also, the switch over to port4 does not occur as soon as port3 exceeds its bandwidth limit. Bandwidth usage has to exceed the limit for a period of time before the switch over takes place. If port3 bandwidth usage drops below the bandwidth limit during this time period, sessions are not switched over to port4. This delay reduces route flapping.

FortiGate usage-based ECMP routing is not actually load balancing, since routes are not distributed evenly among FortiGate interfaces. Depending on traffic volumes, most traffic would usually be processed by the first interface with only spillover traffic being processed by other interfaces.

If you are configuring usage-based ECMP in most cases you should add spillover thresholds to all of the interfaces with ECMP routes. The default spillover threshold is 0 which means no bandwidth limiting. If any interface has a spillover threshold of 0, no sessions will be routed to interfaces lower in the list unless the interface goes down or is disconnected. An interface can go down if **Detect interface status for Gateway Load Balancing** does not receive a response from the configured server.

Determining if an interface has exceeded its Spillover Threshold

You can use the `diagnose netlink dstmac list` CLI command to determine if an interface is exceeding its Spillover Threshold. If the command displays **over_bps=1** the interface is exceeding its threshold. If **over_bps=0** the interface has not exceeded its threshold.

```
dev=Wifi mac=00:00:00:00:00:00 src-vis-os src-vis-host src-vis-user rx_tcp_
mss=0 tx_tcp_mss=0 overspill-threshold=0 bytes=0 over_bps=0 sampler_rate=0
```

Configuring weighted static route load balancing

Configure weighted load balancing to control how the FortiGate unit distributes sessions among ECMP routes by adding weights for each route. Add higher weights to routes that you want to load balance more sessions to.

With the ECMP load balancing method set to weighted, the FortiGate unit distributes sessions with different destination IPs by generating a random value to determine the route to select. The probability of selecting one route over another is based on the weight value of each route. Routes with higher weights are more likely to be selected.

Large numbers of sessions are evenly distributed among ECMP routes according to the route weight values. If all weights are the same, sessions are distributed evenly. The distribution of a small number of sessions; however, may not be even. For example, its possible that if there are two ECMP routes with the same weight; two sessions to different IP addresses could use the same route. On the other hand, 10,000 sessions with different destination IPs should be load balanced evenly between two routes with equal rates. The distribution could be 5000:5000 or 50001:4999. Also, 10 000 sessions with different destination IP addresses should be load balanced as 3333:6667 if the weights for the two routes are 100 and 200.

Weights only affect how routes are selected for sessions to new destination IP addresses. New sessions to IP addresses already in the routing cache are routed using the route for the session already in the cache. So in practice sessions will not always be distributed according to the routing weight distribution.

To add weights to static routes from the web-based manager

1. Go to **Router > Static > Settings**.
2. Set **ECMP Load Balance Method** to **Weighted Load Balance**.
3. Go to **Router > Static > Static Routes**.
4. If needed, add new static routes, for example:

Destination IP/Mask	192.168.20.0/24
Device	port1
Gateway	172.20.110.1
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port2

Gateway	172.20.120.2
Distance	10

5. Go to **Router > Static > Interfaces**.
6. Select a number next to an interface name, and choose **Edit** to change it, or simply double-click the interface name.
7. Set the weight; for example, set the weight of port1 to 100 and the weight of port2 to 200.

Dynamic Routing Overview

This section provides an overview of dynamic routing, and how it compares to static routing. For details on various dynamic routing protocols, see the following chapters for detailed information.

The following topics are included in this section:

What is dynamic routing?
Comparison of dynamic routing protocols
Choosing a routing protocol
Dynamic routing terminology
IPv6 in dynamic routing

What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives routing updates, and dynamically decides which routes are best to go into the routing table. Its this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information on these administrative distances, see Advanced Static Routing on page 242.

This section includes:

- Comparing static and dynamic routing
- Dynamic routing protocols
- Minimum configuration for dynamic routing

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages — for the routing to come together despite obstacles. For example, if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table — if a network administrator doesn't fix a routing problem manually, it may never be fixed, resulting in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making about the optimal route, and using the routing tables of these routers for potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits include more complexity and some overhead: the routing protocol uses some bandwidth for its own administration.

Comparing static and dynamic routing

Feature	Static Routing	Dynamic Routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router Memory Required	Minimal	Can require considerable memory for larger tables
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None - if a route fails it has to be fixed manually	Robust - traffic routed around failures automatically
Convergence	None	Varies from good to excellent

Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route) support. Typically the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example RIP, and BGP use distance vector algorithms, where OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses — one protocol may have fast convergence, while another may be very reliable, and a third is very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- Classful versus classless routing protocols
- Interior versus exterior routing protocols
- Distance vector versus link-state protocols

Classful versus classless routing protocols

Classful or classless routing refers to how the routing protocol handes the IP addresses. In classful addresses there is the specific address, and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with RFC 1519 and most recently with RFC 4632) to keep routing tables from getting too large. With Classful routing, each IP address requires its own entry in the routing table. With Classless routing, a series of addresses can be combined into one entry potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing out of necessity include RIPv2, BGP, IS-IS, and OSPF. Older protocols such as RIPv1 do not support CIDR addresses.

Interior versus exterior routing protocols

The names ***interior*** and ***exterior*** are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol, which prevents them from connecting outside the network without passing through the border. Exterior routers in such a configuration must have both exterior and interior protocols, to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to interior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route — Distance vector and Link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination, and in more advanced routing protocols these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, RFC 1058 which defines RIP v1 states the following:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information — in other words it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed for ever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops however, so this weakness is not as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along only information about networks and devices directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on the FortiGate unit, and one other router configured as well. Some protocols require larger networks to function as designed.

Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF / IS-IS
Interface	yes	yes	yes
Network	yes	yes	yes
AS	local and neighbor	no	yes
Neighbors	at least one	at least one	at least one
Version	no	yes	no
Router ID	no	no	yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information on these dynamic routing protocols, see Routing Information Protocol (RIP) on page 295, Border Gateway Protocol (BGP) on page 332, Open Shortest Path First (OSPF) on page 371, and Intermediate System to Intermediate System Protocol(IS-IS) on page 412.

Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF / IS-IS
Routing algorithm	Distance Vector, basic	Distance Vector, advanced	Link-state
Common uses	Small non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks
Strengths	Fast and simple to implement Near universal support Good when no redundant paths	Graceful restart BFD support Only needed on border routers Summarize routes	Fast convergence Robust Little management overhead No hop count limitation Scalable
Weakness	Frequent updates can flood network Slow convergence Maximum 15 hops may limit network configuration	Required full mesh in large networks can cause floods Route flap Load-balance multihomed networks Not available on low-end routers	Complex No support for unequal cost multipath routing Route summary can require network changes
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 Support	Only in RIPng	Only in BGP4+	Only in OSPF6 / Integrated IS-IS

Routing protocols

- ***Routing Information Protocol (RIP)*** uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.
- ***Border Gateway Protocol (BGP)*** has been the core Internet backbone routing protocol since the mid 1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.
- ***Open Shortest Path First (OSPF)*** is commonly used in large enterprise networks. It is the protocol of choice mainly due to its fast convergence. However, it can be complicated to setup properly.

- ***Intermediate System to Intermediate System (IS-IS) Protocol*** allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware.
- ***Multicast*** addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the "intelligent" part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link, and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information on the routing algorithm used, see Comparison of dynamic routing protocols on page 282.

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of this type of threat. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers — all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When configuring authentication on your network, ensure you configure it the same on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of `123` on an OSPF interface called `ospf_test`, enter the following CLI command:

```
config router ospf
   config ospf-interface
      edit ospf_test
         set authentication md5
         set md5-key 123
      end
   end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems such as network loops which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including

configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem short of a total network failure.

IPv6 Support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols originally supported IPv6, but they all have additions, expansions, or new versions that do support IPv6. For more information, see Routing Information Protocol (RIP) on page 295, Border Gateway Protocol (BGP) on page 332, Open Shortest Path First (OSPF) on page 371, or Intermediate System to Intermediate System Protocol(IS-IS) on page 412.

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- Budget
- Current network size and topology
- Expected network growth
- Available resources for ongoing maintenance

Budget

When making any business decision, the budget must always be considered. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, will need to support your chosen routing protocols. Network management software and routing protocol drivers may be necessary as well to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, either a training course or some hands-on learning time must be budgeted so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets, but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment, and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier static routing works well on small networks. At those networks get larger, routing takes longer, routing tables get very large, and general performance isn't what it could be.

Topology is a concern as well. If all your computers are in one building, its much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don't worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be getting slower, more complex, and there won't be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size, and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before those new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when those new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, this labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, those new routers can help share the load in most dynamic routing configurations. For example if you have 4 OSPF routers and 20,000 external routes those few routers will be overwhelmed. But in a network with 15 OSPF routers they will better be able to handle that number of routes. Be aware though that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

Available resources for ongoing maintenance

As touched on in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator if needed, extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time.
- Routing hardware updates will require time.
- Office reorganizations or significant personnel movement will require time from a networking point of view.
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem.

If the resources to accomplish these tasks are not budgeted, they will either not happen or not happen at the required level to continue operation. This will result in both the network administration staff and the network users being very frustrated.

A lack of maintenance budget will also result in increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

Choosing a routing protocol

One of that hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols including their strongest and weakest points. The steps to choosing your routing protocol are:

1. Answer questions about your network
2. Evaluate your chosen protocol
3. Implement your dynamic routing protocol

Answer questions about your network

Before you can decide what is best for your situation, you need to examine what the details of your situation are such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

It matters if you only have a few computers, or if you have many and if they are all at one location or not as well. All routing protocols can be run on any sized network, however it can be inefficient to run some on very small networks. However, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what application your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service do the users expect from the network?

Different network users have different expectations of the network. Its not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don’t have to chance technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in. Others do not. If security is important to you, be aware of this.

What is your budget — both initial and maintenance?

More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also more secure configurations require still more resources. This includes both set up costs, as well as ongoing maintenance costs. Ignore these costs at the risk of having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test install of that protocol.

The test install is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test install is to prove that it will work on a larger scale on your network. So be sure that the test install mirrors your larger network well enough for you to discover any problems. If its too simplistic, these problems may not appear.

If your chosen protocol does not meet your goals choose a different protocol and repeat the evaluation process until either a protocol meets your needs, or you change your criteria.

Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide as needed during your implementation to help ensure a smooth transition. Examples for each protocol have been included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It become even more complicated when you add to this each routing protocol having slightly different names for similar features, and many configurable features for each protocol.

To better understand dynamic routing, here are some explanations of common dynamic routing terms.

- Aggregated routes and addresses
- Autonomous system (AS)
- Area border router (ABR)
- Neighbor routers
- Route maps

- Access lists
- Bi-directional forwarding detection (BFD)

For more details on a term as it applies to a dynamic routing protocol, see one of Border Gateway Protocol (BGP) on page 332, Routing Information Protocol (RIP) on page 295, or Open Shortest Path First (OSPF) on page 371.

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one. This reduces the amount of space those routes require in the routing tables of the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating you need to decide if its better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information on aggregated routes in BGP, see Border Gateway Protocol (BGP) on page 332, and Border Gateway Protocol (BGP) on page 332.

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

1. Convert the addresses to binary
   ```
   192.168.1.100 = 11000000 10101000 00000001 01100100
   192.168.1.101 = 11000000 10101000 00000001 01100101
   192.168.1.102 = 11000000 10101000 00000001 01100110
   192.168.1.103 = 11000000 10101000 00000001 01100111
   ```
2. Determine the maximum number of matching bits common to the addresses.
   There are 30-bits in common, with only the last 2-bits being different.
3. Record the common part of the address.
   ```
   11000000 10101000 00000001 0110010X = 192.168.1.100
   ```
4. For the netmask, assume all the bits in the netmask are 1 except those that are different which are 0.
   ```
   11111111 11111111 11111111 11111100 = 255.255.255.252
   ```
5. Combine the common address bits and the netmask.
   ```
   192.168.1.100/255.255.255.252
   ```
   Alternately the IP mask may be written as a single number:
   ```
   192.168.1.100/30
   ```
6. As required, set variables and attributes to declare the routes have been aggregated, and what router did the aggregating.

Autonomous system (AS)

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of AS defined by how they are connected to other ASes. A multihomed AS is connected to at least two other ASes and has the benefit of redundancy — if one of those ASes goes down, your AS can still reach the Internet through its other connection. A stub AS only has one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS) you need to have an officially registered ASN from Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

NAs of January 2010, AS numbers are 4 bytes long instead of the former 2 bytes. RFC 4893 introduced 32-bit ASNs, which FortiGate units support for BGP and OSPF.

Do you need your own AS?

The main factors in deciding if you need your own AS or if you should be part of someone else's are:

- exchanging external routing information
- many prefixes should exist in one AS as long as they use the same routing policy
- when you use a different routing protocol than your border gateway peers (for example your ISP uses BGP, and you use OSPF)
- connected to multiple other AS (multi-homed)

You should not create an AS for each prefix on your network. Neither should you be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number to use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers are from 1 to 64,511. The ASNs 0, 54272–64511, and 65535 are reserved by the IANA. These ASNs should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIRs) who then assign ASNs to companies within that RIRs geographic area. Usually these companies are ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The RIRs names and regions are:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific including China, India, and Japan
ARIN	American registry including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet such as test networks, classroom labs, or other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts will happen. It would be very much like your local 192.168.0.0 network being made public — the resulting problems would be widespread.

In 1996, when RFC 1930 was written only 5,100 ASes had been allocated and a little under 600 ASes were actively routed in the global Internet. Since that time many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. RFC 4893 defines 32-bit ASNs, and FortiGate units support these larger ASNs.

Area border router (ABR)

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and with routers external to their AS, often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. Often ABRs run multiple routing protocols to be able to redistribute traffic between different ASes that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains a LSA database for each area that it is connected to. The concept of the edge router is present, but its the edge of the backbone instead of the edge of the OSPF supported ASes.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers, and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality others routers lack. Neighbor routers are sometimes called peers.

Generally neighbor routers must be configured, and discovered by the rest of the network before they can be integrated to the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates, and sent route updates. This can include the redistribution of routes learned from other types of routing. For example if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. Then during your configuration, you can use these route-maps to speed up configuration. The meaningful names ensure fewer mistakes during configuration as well.

The default rule in the route map (which the FortiGate unit applies last) denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
   edit <route_map_name>
      set comments
      config rule
         edit <route_map_rule_id>
            set action
            set match-*
            set set-*
            ...
         end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 332.

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers, or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
   edit <access_list_name>
      set comments
      config rule
```

```
edit <access_list_id>
   set action
   set exact-match
   set prefix
   set prefix6
   set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 332.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF or BFP routers that establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
   config neighbor
      set bfd
end
config router ospf
   set bfd
end
```

Per-VDOM configuration:

```
config system settings
   set bfd
   set bfd-desired-min-tx
   set bfd-required-min-rx
   set bfd-detect-mult
   set bfd-dont-enforce-src-port
end
```

Per-interface (override) configuration:

```
config system interface
   edit <interface_name>
      set bfd enable
      set bfd-desired-min-tx
      set bfd-detect-mult
      set bfd-required-min-rx
   end
```

For more information about BFD in BGP, see Border Gateway Protocol (BGP) on page 332.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — RFC 2080 - Routing Information Protocol next generation (RIPng). See RIP and IPv6.
- **BGP4+** — RFC 2545, and RFC 2858 Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See BGP and IPv6.
- **OSPFv3** — RFC 2740 Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See OSPFv3 and IPv6.
- **Integrated IS-IS** — RFC 5308 for IPv6 support. See Integrated IS-IS.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Admin > Settings**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Routing Information Protocol (RIP)

This section describes the Routing Information Protocol (RIP).

The following topics are included in this section:

RIP background and concepts
Troubleshooting RIP
Simple RIP example
RIPng — RIP and IPv6

RIP background and concepts

This section contains:

- Background
- Parts and terminology of RIP
- How RIP works

Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by RIP, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP benefits include being well suited to smaller networks, is in widespread use, near universal support on routing hardware, quick to configure, and works well if there are no redundant paths. However, RIP updates are sent out node-by-node so it can be slow to find a path around network outages. RIP also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), and the IPv6 version RIPng (see RFC 2080).

RIP v1

In 1988 RIP version 1, defined in RFC 1058, was released. The RFC even states that RIP v1 is based on Linux routed due to it being a “defacto standard”.

It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing, and it does not support CIDR addressing — subnets must all be the same size. Also, route summarization is not possible.

RIP v1 has no router authentication method, so it is vulnerable to attacks through packet sniffing, and spoofing.

RIP v2

In 1993, RIP version 2 was developed to deal with the limitations of RIP v1. It was not standardized until 1998. This new version supports classless routing, and subnets of various sizes.

Router authentication was added in RIP v2 — it supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all.

In RIP v2 the hop count limit remained at 15 to be backwards compatible with RIP v1.

RIP v2 uses multicasting to send the entire routing table to router neighbors, thereby reducing the traffic for devices that are not participating in RIP routing.

Routing tags were added as well, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in RFC 2080, is an extension of RIP2 designed to support IPv6. However, RIPng varies from RIPv2 in that it is not fully backwards compatible with RIPv1.

- RIPng does not support RIPv1 update authentication, it relies on IPsec
- RIPng does not allow attaching tags to routes as in RIPv2
- RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

Parts and terminology of RIP

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

This section includes:

- RIP and IPv6
- Default information originate option
- Update, Timeout, and Garbage timers
- Authentication and key-chain
- Access Lists

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP was released that includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ip6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
```

```
    edit test_tunnel
      set destination 2002:A0A:A01::
      set interface port1
      set source 2002:C0A8:3201::
    end
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

This is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
   set default-information-originate
end
```

Update, Timeout, and Garbage timers

RIP uses various timers to regulate its performance including an update timer, a timeout timer, and a garbage timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers.

The Timeout period should be at least three times longer than the Update period. If the Update timer is smaller than Timeout or Garbage timers, you will experience an error.

You can set the three RIP timers in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
   set timeout-timer
   set update-timer
   set garbage-timer
end
```

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience time outs that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the depute period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the time the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This will result in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication and key-chain

RIP version 2 uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 has no authentication. For authentication to work both the sending and receiving routers must be set to use authentication, and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

Key-chain is a CLI router command. You use this command to manage RIP version 2 authentication keys. You can add, edit or delete keys identified by the specified key number.

This example shows how to configure a key-chain with two keys that are valid sequentially in time. This example creates a key-chain called “rip_key” that has a password of “fortinet”. The accepted and send lifetimes are both set to the same values — a start time of 9:00am February 23, 2010 and an end time of 9:00am March 17, 2010. A second key is configured with a password of “my_fortigate” that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This “rip_key” keychain is then used on the port1 interface in RIP.

```
config router key-chain
```

```
    edit "rip_key"
       config key
       edit 1
          set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
          set key-string "fortinet"
          set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
       next
       edit 2
          set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
          set key-string "my_fortigate"
          set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
       next
       end
    end
config router rip
    config interface
       edit port1
          set auth-keychain "rip_key"
       end
    end
```

The CLI commands associated with authentication keys include:

```
config router key-chain

config router rip
    config interface
       edit <interface>
          set auth-keychain
          set auth-mode
          set auth-string
       end
    end
```

Access Lists

Access lists are filters used by FortiGate unit RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the RIPng or OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
   edit test_list
      config rule
         edit 1
            set prefix 10.10.10.10 255.255.255.255
            set action allow
            set exact-match enable
         next
         edit 2
            set prefix 11.11.11.11 255.255.255.255
            set action allow
            set exact-match enable
         end
      end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
      end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase . Enter the following command:

```
config router rip
   config offset-list
      edit 5
         set access-list test_list
         set direction in
         set interface port1
         set offset 3
         set status enable
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it's relatively simple to configure RIP on FortiGate

units.

From RFC 1058:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

This section includes:

- RIP versus static routing
- RIP metric — hop count
- The Bellman–Ford routing algorithm
- Passive versus active RIP interfaces
- RIP packet structure

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both RIP and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate unit can only send it to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so your FortiGate unit can send the packet farther towards its destination before it has to be routed again towards its destination. RIP reduces the amount of table lookups and therefore fewer network resources than static routing. Also since RIP is updated on neighboring routes it is aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

RIP metric — hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in RIP packet structure on page 305, the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it becomes very easy to reach the upper limit. This higher weighting will effectively limit the size of your network depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the offset command to artificially increase the hop count of a route. Doing this will make this route less preferred, and in turn it will get less traffic. Offsetting routes is useful when you have network connections of different bandwidths, different levels of reliability, or different costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see Access Lists on page 299.

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let's look at a network with 4 routers — routers 1 through 4. The distance from router1 to router2 is 2 hops, 1 to 3 is 3 hops, and 2 to 3 is 4 hops. Router4 is only connected to routers 2 and 3, each distance being 2 hops.

1. Router1 finds all the distance to the other three routers — router 2 is 2, router 3 is 3. Router1 doesn't have a route to router 4.
2. Routers 2 through 4 do the same calculations from their point of views.
3. Once router 1 gets an update from router 2 or 3, it will get their route to router 4. At that point it now has a route to router 4 and installs that in its local table.
4. If router1 gets an update from router3 first, it has a hop count of 5 to reach router4. But when router2 sends its update, router1 will go with router2's shorter 4 hops to reach router4. Future updates don't change this unless they are shorter than 4 hops, or the routing table route goes down.

RIP algorithm example in 4 steps

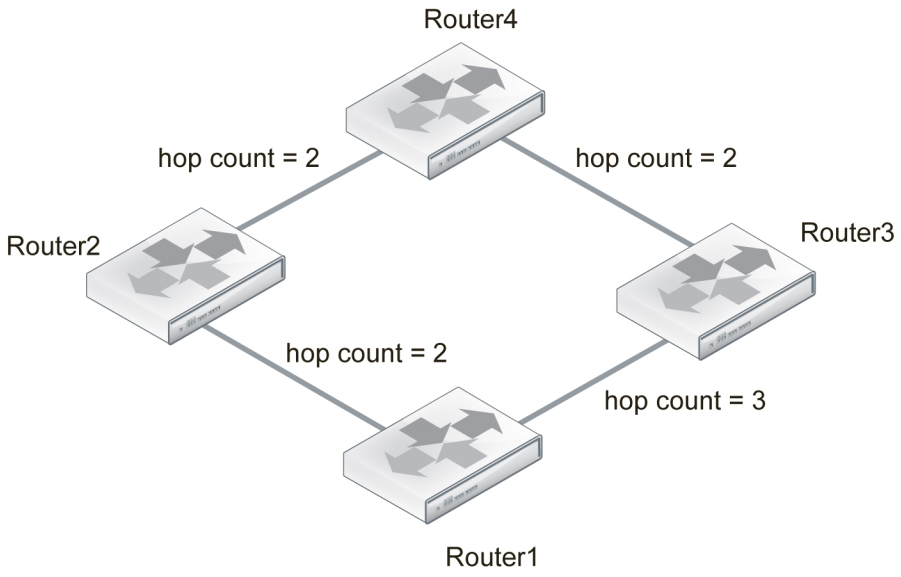
Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

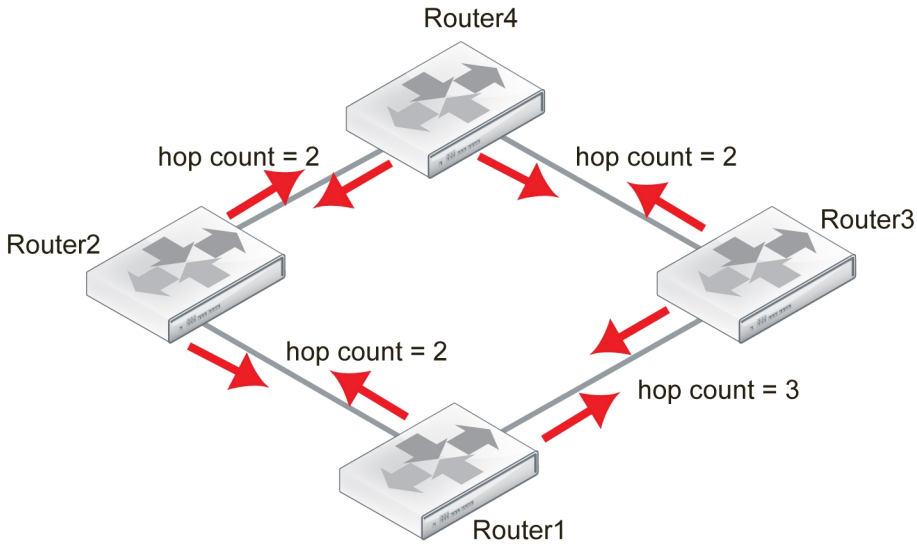
- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.



Step 2

All routers do the same as Router1, and send out updates containing their routing table.

Note that Router1 and Router4 do not update each other, but rely on Router2 and Router3 to pass along accurate updates.

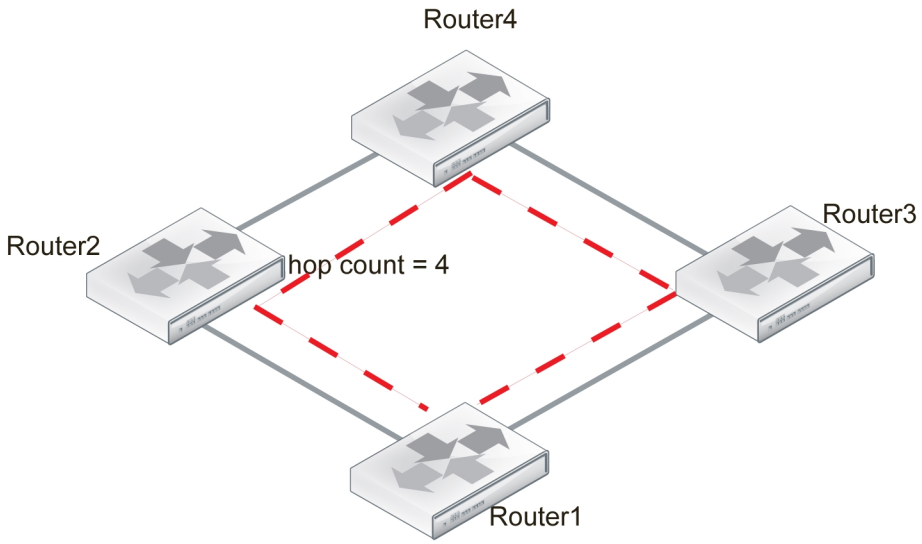


Step 3

Each router looks at the updates it has received, and adds any new or shorter routes to its table.

Router1 updated table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 or 5 hops.

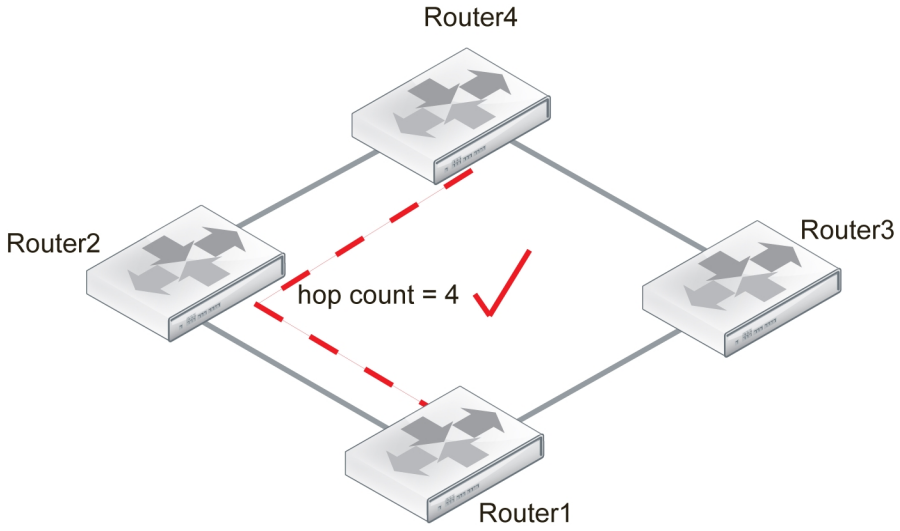


Step 4

Router1 installs the shortest route to Router4, and the other routes to it are removed from the routing table.

Router1 complete table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 hops.



The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, so less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see RIP packet structure on page 305.

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size

by reducing the hop count limit. Also other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest but also the fastest or more reliable routes as you choose.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down, which wastes time and network resources.

Passive versus active RIP interfaces

Normally the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

An standard interface that supports RIP is active by default — it both sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates — it just listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that would be sending out essentially the same updates all the time.

The following example shows how to create a passive RIP v2 interface on port1, using MD5 authentication and a key-chain called `passiveRIPv2` that has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - web-based manager

1. Go to **Router > Dynamic > RIP**.
2. Next to **Interfaces**, select **Create**.
3. Select port1 as the **Interface**.
4. Select 2 as both the **Send Version** and **Receive Version**.
5. Select MD5 for **Authentication**.
6. Select the `passiveRIPv2` **Key-chain**.
7. Select **Passive Interface**.
8. Select **OK** to accept this configuration, and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication- CLI

```
config router rip
   config interface
      edit port1
         set send-version2-broadcast disable
         set auth-keychain "passiveRIPv2"
         set auth-mode md5
         set receive-version 2
         set send-version 2
      end
   end
```

RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the RIP protocol, and better configure your network for it.

This section provides information on the contents of RIP 1 and RIP 2 packets.

RIP version 1

RIP version 1, or RIP IP packets are 24 bytes in length, with some empty areas left for future expansion.

RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

A RIP 1 packet contains the following fields:

- **Command** — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.
- **Version** — Specifies the RIP version used. This field can signal different potentially incompatible versions.
- **Zero field** — This field defaults to zero, and is not used by RFC 1058 RIP.
- **Address-family identifier (AFI)** — Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.
- **IP Address** — Specifies the IP address for the entry.
- **Metric** — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

RIP version 2

RIP version 2 has more features than RIP 1, which is reflected in its packets which carry more information. All but one of the empty zero fields in RIP 1 packets are used in RIP 2.

RIP 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag
4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric	

A RIP 2 packet contains fields described above in RIP 1, as well as the following:

- **Unused** — Has a value set to zero, and is intended for future use
- **Route tag** — Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.
- **Subnet mask** — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.
- **Next hop** — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the FortiOS Handbook Troubleshooting chapter.

This section includes:

- Routing Loops
- Holddowns and Triggers for updates
- Split horizon and Poison reverse updates
- Debugging IPv6 on RIPng

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems getting information to its destination and also prevents it from returning to the source to report the inaccessible destination.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the RIP routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic, and are covered in Advanced Static Routing on page 242.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > Config > SNMP**.
2. Enable **SMTP Agent** and select **Apply**.
   Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
3. Under **SNMP v1/v2** or **SNMP v3** as appropriate, select **Create New**.
   SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The **Port** should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

   SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify. You can also specify the network **Interface**, or leave it as **ANY**.
Queries	Enable **v1** and/or **v2** as needed. The **Port** should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include **CPU usage is high**, **Memory is low**, and possibly **Log disk space is low**.If there are problems the log will be filling up quickly, and the FortiGate unit's resources will be overused.

5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful in dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor and e-mail alerts

1. Go to **Router > Static > Settings** and select **Create New** under **Link Health Monitor**.
2. Enter the **Ping Server** IP address under **Gateway** and select the **Interface** that connects to it.
3. Set the **Probe Interval** (how often to send a ping), and **Failure Threshold** (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

To configure notification of failed gateways

1. Go to **Log & Report > Report > Local** and enable **Email Generated Reports**.
2. Enter your email details.
3. Select **Apply**.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. This is same idea as police pulling over a car and asking the driver where they have been, and what the conditions were like.

The method used in the troubleshooting sections Debugging IPv6 on RIPng on page 310 and on debugging the packet flow apply here as well. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.

2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Holddowns and Triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there is a change to the routing table. If your network has many RIP routers, these updates can start to slow down your network. Also if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out, and help prevent a potential flood.

Holddown Timers

The holddown timer activates when a route is marked down. Until the timer expires, the router does not accept any new information about that route. This is very useful if you have a flapping route because it will prevent your router from sending out updates and being part of the problem in flooding the network. The potential down side is if the route comes back up while the timer has not expired, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table will only be updated when a specific request is sent to update, as opposed to every time the routing table changes. Updates are also triggered when a unit is ‘powered on’, which can include addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let’s call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A’s route to get to C. This route is A-B-C, so it will loop endlessly between A and B.

This situation is called a split horizon because from B’s point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse “poisons” routes away from the destination that use the current router in their route to the destination. This “poisoned” route is marked as unreachable for routers that cannot use it. In RIP this means that route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

For more information, see Troubleshooting RIP on page 307.

Simple RIP example

This is an example of a typical medium sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the Internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configuring the FortiGate units system information
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network — Sales, R&D, and Accounting. Each network has routers that are not running RIP as well as FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

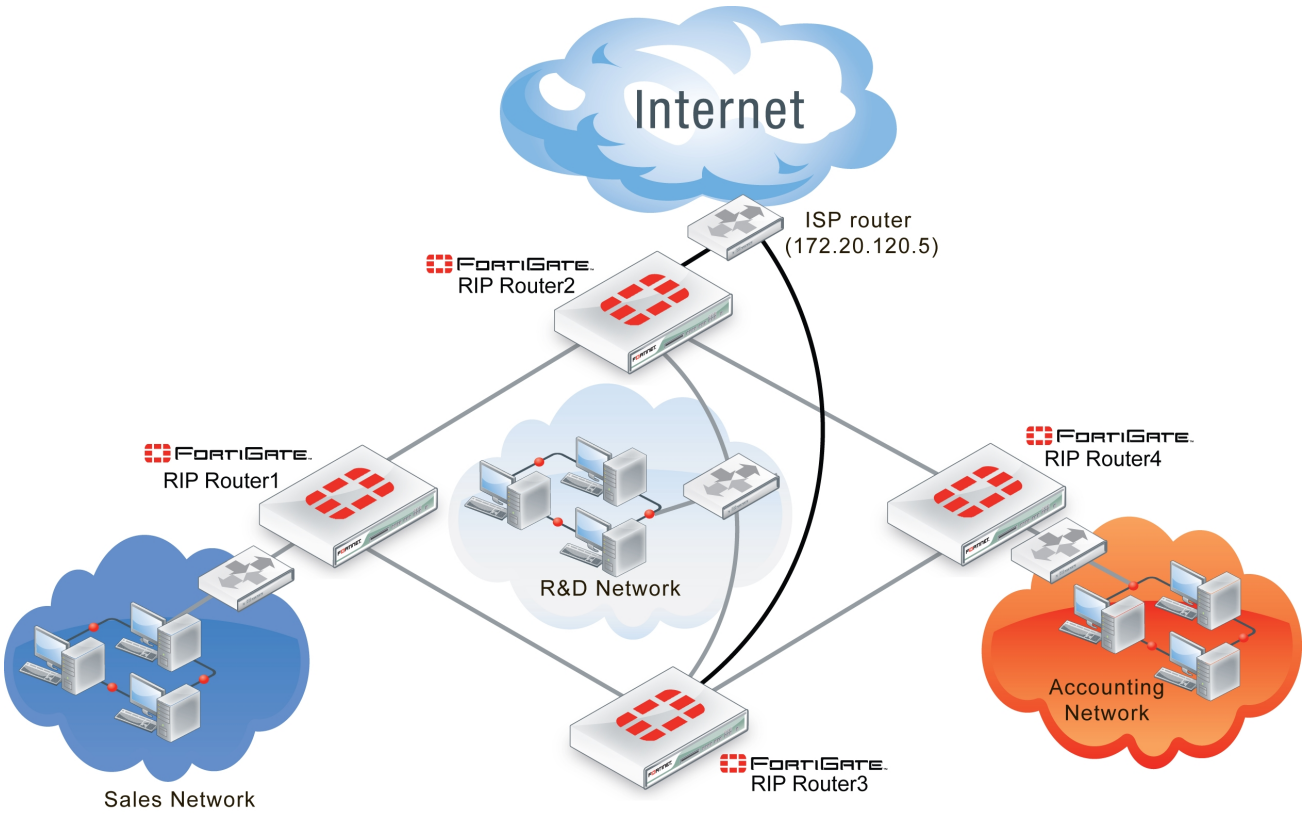
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows. Note that the Interfaces that connect Router2 and Router3 also connect to the R&D network.

RIP example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101
	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
R&D	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
	Router4	port1 (internal)	10.14.101.104
Accounting		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Network topology for the simple RIP example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in the diagram above.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring FortiGate unit RIP router information
- Configuring other networking devices
- Testing network configuration

Configuring the FortiGate units system information

Each FortiGate unit needs their hostname, and interfaces configured.

For IP numbering, Router2 and Router3 use the other routers numbering where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - web-based manager

1. Go to **System > Dashboard > Status > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router1”.
3. Go to **Router > Static > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9. Edit port2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2
IP/Network Mask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router1 system information - CLI

```
config system global
   set hostname Router1
end

config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.11.201.102
   next
   edit 2
      set device “port3”
      set distance 45
      set gateway 10.11.202.103
   end
end

config system interface
   edit port1
      set alias internal
      set ip 10.11.101.101/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal sales network”
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.101/255.255.255.0
      set description “Link to R&D network & Internet through Router2”
   next
```

```
    edit port3
       set alias router3
       set ip 10.11.202.101/255.255.255.0
       set allowaccess https ssh ping
       set description "Link to R&D network & Internet through Router2"
    end
end
```

To configure Router2 system information - web-based manager

1. Go to **System > Dashboard > Status > System Information**.
2. Next to **Host Name** select **Change**, and enter "Router2".
3. Go to **Router > Static > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **System > Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet through ISP
Administrative Status	Up

To configure Router2 system information - CLI

```
config system global
   set hostname Router2
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.102/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal RnD network and Router3”
   next
   edit port2
      set alias router1
      set allowaccess https ssh ping
      set ip 10.11.201.102/255.255.255.0
      set description “Link to Router1”
   next
   edit port3
      set alias router3
      set ip 10.14.202.102/255.255.255.0
      set allowaccess https ssh ping
      set description “Link to Router4”
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.102/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router3 system information - web-based manager

1. Go to **System > Dashboard > Status > System Information**.
2. Next to **Host Name** select **Change**, and enter "Router3".
3. Go to **Router > Static > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **System > Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet and ISP
Administrative Status	Up

To configure Router3 system information - CLI

```
config system global
   set hostname Router3
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.12.101.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal RnD network and Router2”
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.103/255.255.255.0
      set description “Link to Router1”
   next
   edit port3
      set alias router3
      set ip 10.14.202.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Link to Router4”
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.103/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router4 system information - web-based manager

1. Go to **System > Dashboard > Status > System Information**.
2. Next to **Host Name** select **Change**, and enter "Router4".
3. Go to **Router > Static > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **System > Network > Interfaces**.
7. Edit port 1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9. Edit port 2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2

IP/Network Mask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port 3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router4 system information - CLI

```
config system global
   set hostname Router4
end
config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.14.201.102
   next
   edit 2
      set device “port3”
      set distance 45
      set gateway 10.14.202.103
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.14.101.104/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal sales network”
   next
   edit port2
      set alias router2
      set allowaccess https ssh ping
      set ip 10.14.201.104/255.255.255.0
      set description “Link to R&D network & Internet through Router2”
   next
   edit port3
      set alias router3
      set ip 10.14.202.104/255.255.255.0
      set allowaccess https ssh ping
```

```
        set description "Link to R&D network & Internet through Router2"
    end
end
```

Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

For each FortiGate unit the following steps will be taken:

- Configure RIP version used
- Redistribute static networks
- Add networks serviced by RIP
- Add interfaces that support RIP on the FortiGate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure RIP settings on Router1 and Router4 - web-based manager

1. Go to **Router > Dynamic > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:
   - 10.11.0.0/255.255.0.0
   - 10.12.0.0/255.255.0.0
   - 10.14.0.0/255.255.0.0
   - 172.20.120.0/255.255.255.0
6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router2)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router3)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router1 and Router4 - CLI

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configure RIP settings on Router2 and Router3- web-based manager

1. Go to **Router > Dynamic > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:

- 10.11.0.0/255.255.0.0
- 10.12.0.0/255.255.0.0
- 10.14.0.0/255.255.0.0
- 172.20.120.0/255.255.255.0

6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router1)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router4)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

9. For interface, select **Create** and set the following information.

Interface	port4 (ISP)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router2 and Router3- web-based manager

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
      edit "port4"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your network such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the Internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult Simple RIP example on page 311.

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

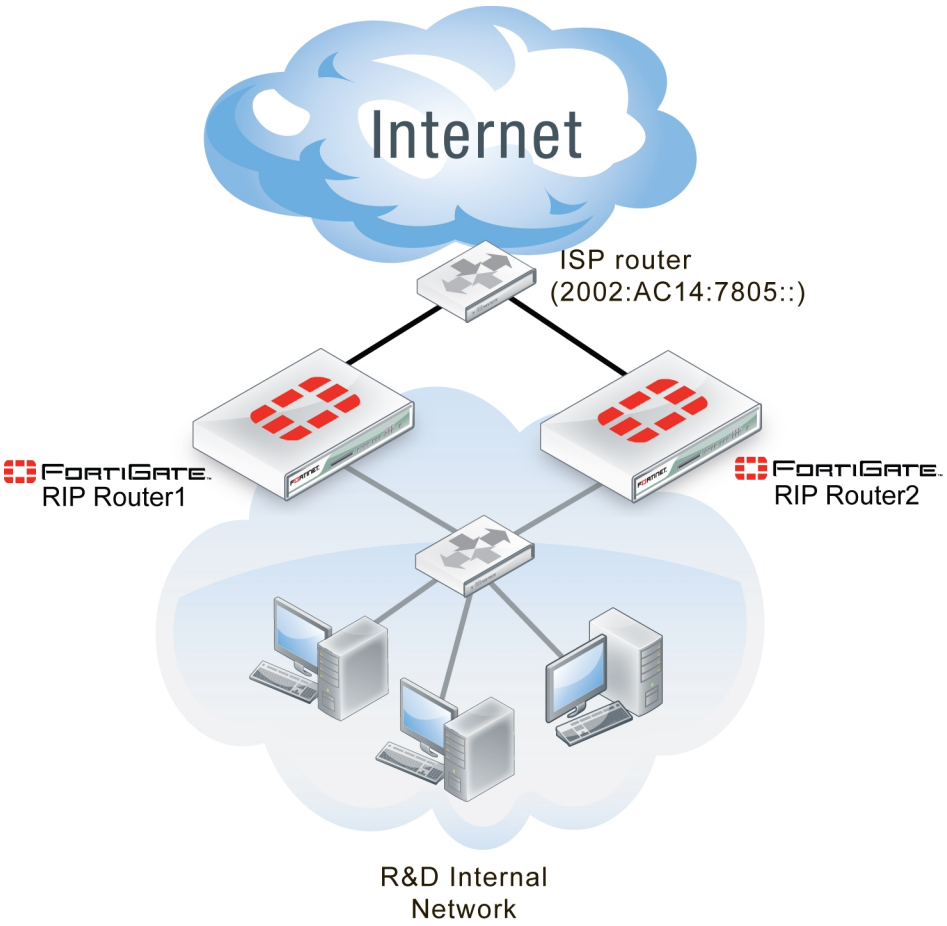
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

RIP example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPV6 RIPng example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.

- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter “Router1”.
4. Go to **System > Config > Features**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router1 - CLI

```
config system global
   set hostname Router1
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description “Internal RnD network”
      config ipv6
```

```
      set ip6-address 2002:a0b:6565::/0
   end
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and Internet"
   config ipv6
      set ip6-address 2002:AC14:7865::
   end
end
```

To configure system information on Router2 - web-based manager

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Config > Features**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router2 - CLI

```
config system global
   set hostname Router2
   set gui-ipv6 enable
end
config system interface
```

```
edit port1
   set alias internal
   set allowaccess https ping ssh
   set description "Internal RnD network"
   config ipv6
      set ip6-address 2002:a0b:6566::/0
   end
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and Internet"
   config ipv6
      set ip6-address 2002:AC14:7866::
   end
end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6566::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

To configure RIPng on Router2 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
```

```
config neighbor
   edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
   next
   edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
   end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

For troubleshooting problems with RIP, see RIPng — RIP and IPv6 on page 326.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Border Gateway Protocol (BGP)

This section describes Border Gateway Protocol (BGP).

The following topics are included in this section:

BGP background and concepts
Troubleshooting BGP
Dual-homed BGP example
Redistributing and blocking routes in BGP

BGP background and concepts

The border gateway protocol contains two distinct subsets — internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together, and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

The following topics are included in this section:

- Background
- Parts and terminology of BGP
- How BGP works

Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in RFC 1771. That RFC has since been replaced by the more recent RFC 4271. The main benefits of BGP-4 are classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in RFC 2858 and RFC 2545.

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. In doing so, BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here as they are common to other dynamic routing protocols as well. When determining your network topology, note that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. For more information on parts of BGP that are not listed here, see Dynamic Routing Overview on page 279.

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the FortiGate CLI Reference.

IPv6 BGP commands include:

```
config router bgp
   set activate6 {enable | disable}
   set allowas-in6 <max_num_AS_integer>
   set allowas-in-enable6 {enable | disable}
   set as-override6 {enable | disable}
   set attribute-unchanged6 [as-path] [med] [next-hop]
   set capability-default-originate6 {enable | disable}
   set capability-graceful-restart6 {enable | disable}
   set capability-orf6 {both | none | receive | send}
   set default-originate-route-map6 <routemap_str>
   set distribute-list-in6 <access-list-name_str>
   set distribute-list-out6 <access-list-name_str>
   set filter-list-in6 <aspath-list-name_str>
   set filter-list-out6 <aspath-list-name_str>
   set maximum-prefix6 <prefix_integer>
   set maximum-prefix-threshold6 <percentage_integer>
   set maximum-prefix-warning-only6 {enable | disable}
   set next-hop-self6 {enable | disable}
   set prefix-list-in6 <prefix-list-name_str>
   set prefix-list-out6 <prefix-list-name_str>
   set remove-private-as6 {enable | disable}
   set route-map-in6 <routemap-name_str>
   set route-map-out6 <routemap-name_str>
   set route-reflector-client6 {enable | disable}
   set route-server-client6 {enable | disable}
   set send-community6 {both | disable | extended | standard}
   set soft-reconfiguration6 {enable | disable}
   set unsuppress-map6 <route-map-name_str>
   config network6
   config redistribute6
end
```

Roles of routers in BGP networks

Dynamic routing has a number of different roles routers can fill such as those covered in Dynamic Routing Overview on page 279. BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors (RR)

Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers, are not treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise these routers will not be seen as peers, but instead as simply other routers on the network that don't support BGP. You can optionally use MD5 authentication to password protect BGP sessions with those neighbors. (see RFC 2385).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

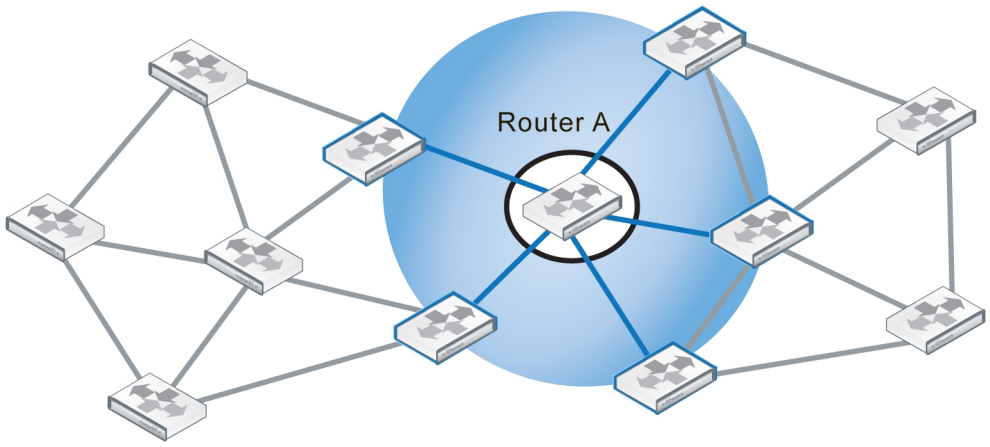
```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In Figure 1, Router A is directly connected to five other routers in a network that contains 12 routers overall. These routers, the ones in the blue circle, are Router A's peers or neighbors.

Router A and its 5 peer routers



As a minimum, when configuring BGP neighbors you must enter their IP address, and the AS number (remote-as). This is all the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
```

```
    config neighbor
       edit <neighbor_address_ipv4>
          set activate {enable | disable}
          set advertisement-interval <seconds_integer>
          set allowas-in <max_num_AS_integer>
          set allowas-in-enable {enable | disable}
          set as-override {enable | disable}
          set attribute-unchanged [as-path] [med] [next-hop]
          set bfd {enable | disable}
          set capability-default-originate {enable | disable}
          set capability-dynamic {enable | disable}
          set capability-graceful-restart {enable | disable}
          set capability-orf {both | none | receive | send}
          set capability-route-refresh {enable | disable}
          set connect-timer <seconds_integer>
          set description <text_str>
          set distribute-list-in <access-list-name_str>
          set distribute-list-out <access-list-name_str>
          set dont-capability-negotiate {enable | disable}
          set ebgp-enforce-multihop {enable | disable}
          set ebgp-multihop {enable | disable}
          set ebgp-multihop-ttl <seconds_integer>
          set filter-list-in <aspath-list-name_str>
          set filter-list-out <aspath-list-name_str>
          set holdtime-timer <seconds_integer>
          set interface <interface-name_str>
          set keep-alive-timer <seconds_integer>
          set maximum-prefix <prefix_integer>
          set maximum-prefix-threshold <percentage_integer>
          set maximum-prefix-warning-only {enable | disable}
          set next-hop-self {enable | disable}
          set passive {enable | disable}
          set password <string>
          set prefix-list-in <prefix-list-name_str>
          set prefix-list-out <prefix-list-name_str>
          set remote-as <id_integer>
          set remove-private-as {enable | disable}
          set retain-stale-time <seconds_integer>
          set route-map-in <routemap-name_str>
          set route-map-out <routemap-name_str>
          set route-reflector-client {enable | disable}
          set route-server-client {enable | disable}
          set send-community {both | disable | extended | standard}
          set shutdown {enable | disable}
          set soft-reconfiguration {enable | disable}
          set strict-capability-match {enable | disable}
          set unsuppress-map <route-map-name_str>
          set update-source <interface-name_str>
          set weight <weight_integer>
       end
    end
end
```

Route reflectors (RR)

Route reflectors in BGP concentrate route updates so other routers need only talk to the route reflectors to get all the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP route reflectors are defined in RFC 1966.

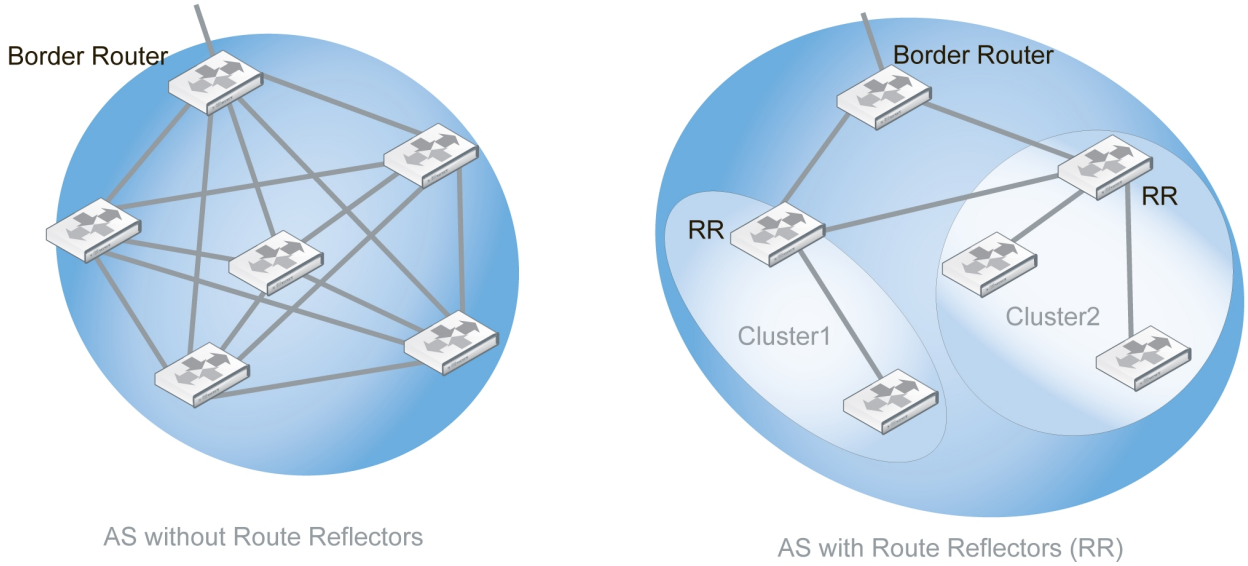
In a BGP route reflector configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other route reflectors and border routers. Only the reflectors need to be configured, not the clients — the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since route reflectors are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically don't require route reflectors (RR). However, RR is a useful feature for large companies, where their AS may include 100 routers or more. For example, for a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions — just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. From these numbers, its plain that updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how route reflectors can improve the situation when only six routers are involved. The AS without route reflectors requires 15 sessions between the routers. In the AS with route reflectors, the two route reflectors receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster as well as other route reflectors and pass them on to the border router. The RR configuration only require six sessions. This example shows a reduction of 60% in the number of required sessions.

Required sessions within an AS with and without route reflectors



AS without Route Reflectors

AS with Route Reflectors (RR)

The BGP commands related to route reflectors includes:

```
config router bgp
   config neighbor
```

```
        set route-reflector-client {enable | disable}
        set route-server-client {enable | disable}
    end
end
```

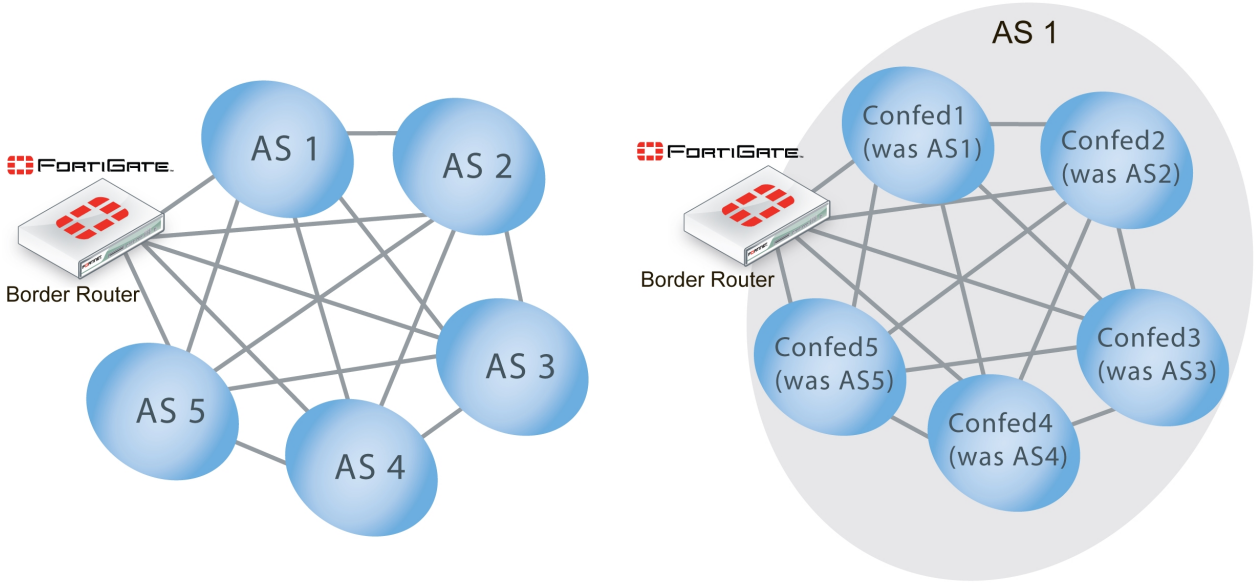
Confederations

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network, and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in RFC 3065 and RFC 1965.

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications in that many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, requiring few changes. Any additional permanent changes can then be implemented over time as required. The figure below shows the group of ASs before merging, and the corresponding confederations afterward as part of the single AS with the addition of a new border router. It should be noted that after merging if the border router becomes a route reflector, then each confederation only needs to communicate with one other router, instead of five others.

AS merging using confederations



Multiple ASes before merging

Combined AS with confederations and new FortiGate unit border router

Confederations and route reflectors perform similar functions — they both sub-divide large ASes for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, where routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
   set confederation-identifier <peerid_integer>
end
```

BGP conditional advertisements

Normally, routes are propagated regardless of the existence of a different path. The BGP conditional advertisement feature allows a route not to be advertised based on existence or non-existence of other routes. With this new feature, a child table under bgp.neighbor is introduced. Any route matched by one of the route-map specified in the table will be advertised to the peer based on the corresponding condition route-map.

You can enable and disable conditional advertisements using the CLI.

To configure BGP conditional advertisements - CLI:

```
config router bgp
   set as 3
      config neighbor
         edit "10.10.10.10"
            set remote-as 3
               config conditional-advertise
                  edit "route-map-to-match-sending"
                     set condition-routemap "route-map-to-match-condition"
                     set condition-type [exist | non-exist]
                  next
               end
            next
         end
```

BGP Neighbor Groups

The BGP Neighbor Groups feature allows a large number of neighbors to be configured automatically based on a range of neighbors' source addresses.

To configure BGP Neighbor Groups - CLI:

Start by adding a BGP neighbor group:

```
config router bgp
   config neighbor-group
      edit <neighbor-group-name>
         set remote-as 100
   ...
```

(All options for BGP neighbor are supported except `password`.)

```
end
```

Then add a BGP neighbor range:

```
config router bgp
   config neighbor-range
      edit 1
         set prefix 192.168.1.0/24
         set max-neighbor-num 100
         set neighbor-group <neighbor-group-name>
      next
```

```
end
```

Network Layer Reachability Information (NLRI)

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers, and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that when combined are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route, and are modified as required along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

AS_PATH	A list of ASes a route has passed through. See AS_PATH on page 339.
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. See MULTI_EXIT_DESC (MED) on page 340.
COMMUNITY	Used to apply attributes to a group of routes. See COMMUNITY on page 341.
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. See NEXT_HOP on page 341.
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. See ATOMIC_AGGREGATE on page 341.
ORIGIN	Used to determine if the route is from the local AS or not. See ORIGIN on page 342.
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED)

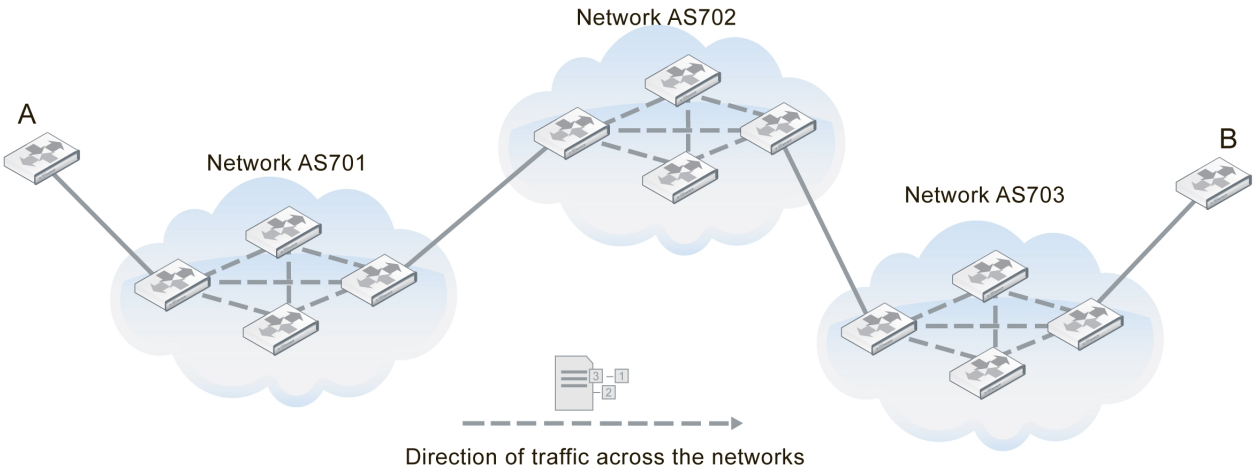
Inbound policies on FortiGate units can change the NEXT-HOP,LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that routers AS in it. The figure below shows the route between router A and router B. The AS_PATH from A to B would read 701,702,703 for each AS the route passes through.

As of the start of 2010, the industry upgraded from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers. FortiOS supports 4-byte AS_PATHs in its BGP implementation.

AS_PATH of 701,702, 703 between routers A and B



The BGP commands related to AS_PATH include:

```
config router bgp
   set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC (MED)

BGP AS systems can have one or more routers that connect them to other ASes. For ASes with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the Multi-Exit Discriminator (MED) attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information which can be suspicious — possibly a hacking attempt or an attack on the network. At best it signifies an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
   set always-compare-med {enable | disable}
   set bestpath-med-confed {enable | disable}
   set bestpath-med-missing-as-worst {enable | disable}
   set deterministic-med {enable | disable}
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
   end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see RFC 1997). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
   set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the config neighbor, set next-hop-self command.

The BGP commands related to NEXT_HOP include:

```
config router bgp
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
      set next-hop-self {enable | disable}
   end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit doesn't specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC_AGGREGATE include:

```
config router route-map
   edit <route_map_name>
      config rule
      edit <route_map_rule_id>
         set set-aggregator-as <id_integer>
         set set-aggregator-ip <address_ipv4>
         set set-atomic-aggregate {enable | disable}
      end
   end
end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are by default higher priority than external routes (EBGP). However incomplete ORIGINs are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
   edit <route_map_name>
      set comments <string>
      config rule
      edit <route_map_rule_id>
         set match-origin {egp | igp | incomplete | none}
      end
   end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other, and establish a connection they go from the idle state, through the various states until they reach the established state. An error can cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used such as multiprotocol extensions that can include IPv6 and VPNs.

IBGP versus EBGP

When you read about BGP, often you see EBGP or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASes) where interior BGP (IBGP) involves packets that stay within a single AS. For example the AS_PATH attribute is only useful for EBGP where routes pass through multiple ASes.

These two modes are important because some features of BGP are only used for one of EBGP or IBGP. For example confederations are used in EBGP, and route reflectors are only used in IBGP. Also routes learned from IBGP have priority over EBGP learned routes.

FortiGate units have some commands specific to EBGP. These include:

- automatically resetting the session information to external peers if the connection goes down — `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (must also configure local and internal distances if this is set) — `set distance-external <distance_integer>`
- enforcing EBGP multihops and their TTL (number of hops) — `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

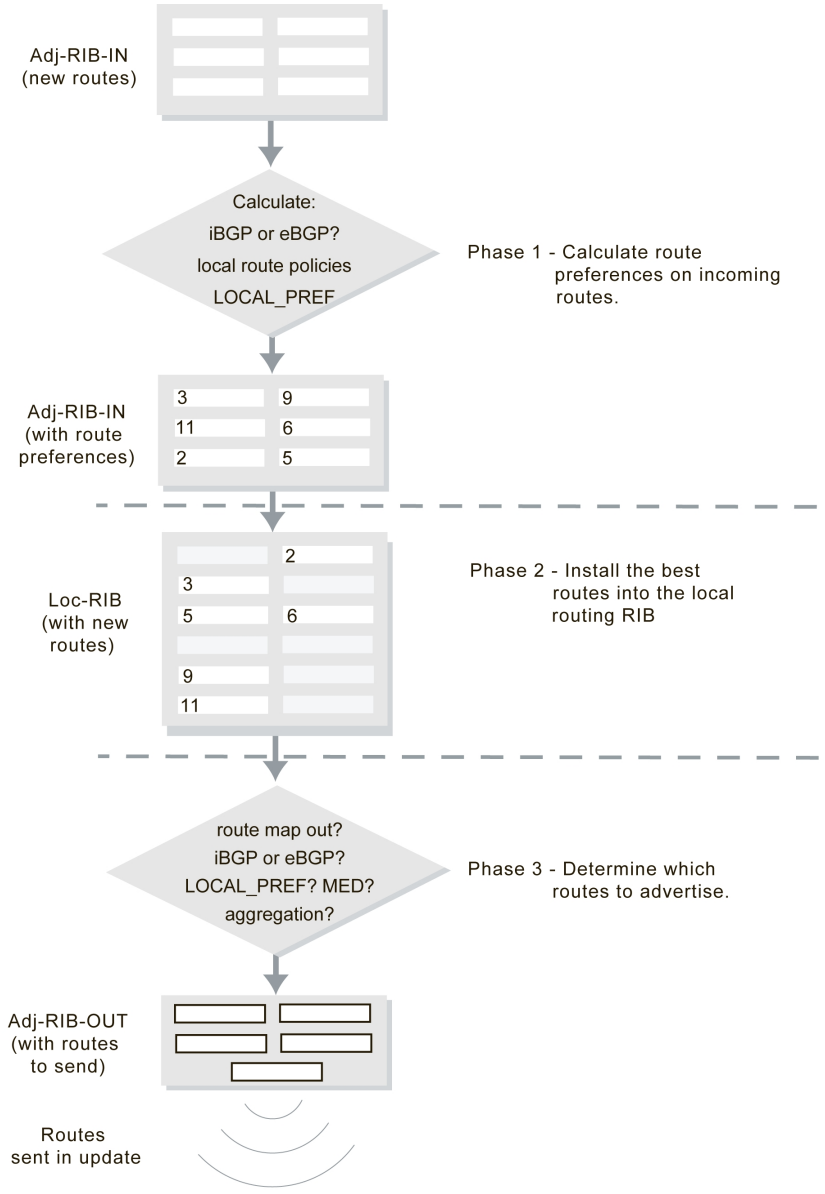
BGP path determination — which route to use

Firstly, recall that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute to enable an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates, or when the FortiGate unit sends out BGP updates.

Three phases of BGP routing decision



Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRLI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to

ensure the destination is reachable. If it is reachable, the AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing enables the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see Dynamic Routing Overview on page 279.

The ATOMIC_AGGREGATE attribute informs routers that the route has been aggregated, and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
   config aggregate-address
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix <address_ipv4mask>
      set summary-only {enable | disable}
   end
   config aggregate-address6
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix6 <address_ipv6mask>
      set summary-only {enable | disable}
   end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically the problems with a BGP network that has been configured, involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables which creates a lot of administration traffic on the network. And the same traffic happens again when that router comes back online. If the problem is something like a faulty network cable that wobbles on and offline every 10 seconds, there could easily be overwhelming amounts of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with route flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holddown timer
- Dampening
- Graceful restart
- Bi-directional forwarding detection (BFD)

Holddown timer

The first line of defence to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holddown timer won't allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit — for the duration of the other outages there will be no changes because the Fortigate unit is essentially treating this router as down. After the timer expires, if the route is still flapping it will happen all over again.

Even if the route isn't flapping — if it goes down, comes up, and stays back up — the timer still counts down and the route is ignored for the duration of the timer. In this situation the route will be seen as down longer than it really is, but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holddown timer.

How to configure the holddown timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holddown timer.

For example, your network has two routes that you want to set the holddown timer for. One is your main route (to 10.12.101.4) that all your Internet traffic goes through, and it can't be down for long if its down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holddown timer for the main route should be fairly short, lets say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default or even longer since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
   config neighbor
   edit 10.12.101.4
      set holddown-timer 60
   next
   edit 10.13.101.4
      set holddown-timer 180
   next
   end
end
```

Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening the flapping still occurs, but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second starts a timer where the router will not use that route — it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life after which a route flap will only be suppressed for half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
```
or
```
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
   set dampening {enable | disable}
```

```
    set dampening-max-suppress-time <minutes_integer>
    set dampening-reachability-half-life <minutes_integer>
    set dampening-reuse <reuse_integer>
    set dampening-route-map <routemap-name_str>
    set dampening-suppress <limit_integer>
    set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded, but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table — if there is a flap the HA cluster routing table will be out of date.

For example, your FortiGate unit is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting—when a router plans to go offline, it will send out a message to its neighbors how long it expects to be before being back online. That way its neighbor routers don't remove it from their routing tables. However if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

Scheduled time offline

Graceful restart is a means for a router to advertise it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software, and also neighboring BGP routers.

For example, if a neighbor of your FortiGate unit, with an IP address of 172.20.120.120, supports graceful restart, enter the command:

```
config router bgp
   config neighbor
   edit 172.20.120.120
      set capability-graceful-restart enable
   end
end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit offline, enter the command:

```
config router bgp
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are:

```
config router bgp
   set graceful-restart { disable| enable}
   set graceful-restart-time <seconds_integer>
   set graceful-stalepath-time <seconds_integer>
   set graceful-update-delay <seconds_integer>
   config neighbor
      set capability-graceful-restart {enable | disable}
   end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it is restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart and check its routes and take care of them if needed after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it is done restarting.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly allowing faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for the FortiGate unit, it could be disabled only for a single interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the FortiGate CLI Reference.

BFD can only be configured through the CLI.

The BGP commands related to BFD are:

```
config system {setting | interface}
   set bfd {enable | disable | global}
   set bfd-desired-mix-tx <milliseconds>
   set bfd-detect-mult <multiplier>
   set bfd-required-mix-rx <milliseconds>
   set bfd-dont-enforce-src-port {enable | disable}

config router bgp
   config neighbor
      edit <neighbor_address_ipv4>
```

```
        set bfd {enable | disable}
    end
end

get router info bfd neighbor
execute router clear bfd session <src_ipv4> <dst_ipv4> <interface>
```

The `config system` commands allow you to configure whether BFD is enabled in a particular unit/vdom or individual interface, and how often the interface requires sending and receiving of BFD information.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to make use of it.

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing, and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent unneeded updates, and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about — the 2 ISP border routers, and the FortiGate unit. This means the FortiGate unit will only have two neighbor routers to configure.

This configuration has the added benefit of being easy to expand if the Company wants to add a remote office in the future.

To keep the configuration simple, the Company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web-mail.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Configuring other networking devices
- Testing this configuration

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- Redundant Internet connection that essentially never fails
- Faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- Load balancing traffic to your Company network
- Easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- Easier to create protection policies for different traffic through a specific ISP

Some companies require reliable Internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences could easily be life or death.

Dual homing is extra expense for the second ISP connection, and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues, and dual homing is the same category. BGP does not inherently deal well with load balancing, or getting default routes through BGP. Ideally one connect may be best for certain destinations, but it may not have that traffic routed to it making the load balancing less than perfect. This kind of fine tuning can be very time consuming, and usually results in a best effort situation.

When dual homing is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problems with this situation are that your traffic may not have the bandwidth it needs, and you will be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening you can turn on asymmetric routing on the FortiGate unit (config system settings, set asymmetric enable) to verify that really is the problem. Turn this feature off once this is established since it disables many features on the FortiGate by disabling stateful inspection. Solutions for this problem can include using static routes for default routes instead of learning them through BGP, or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

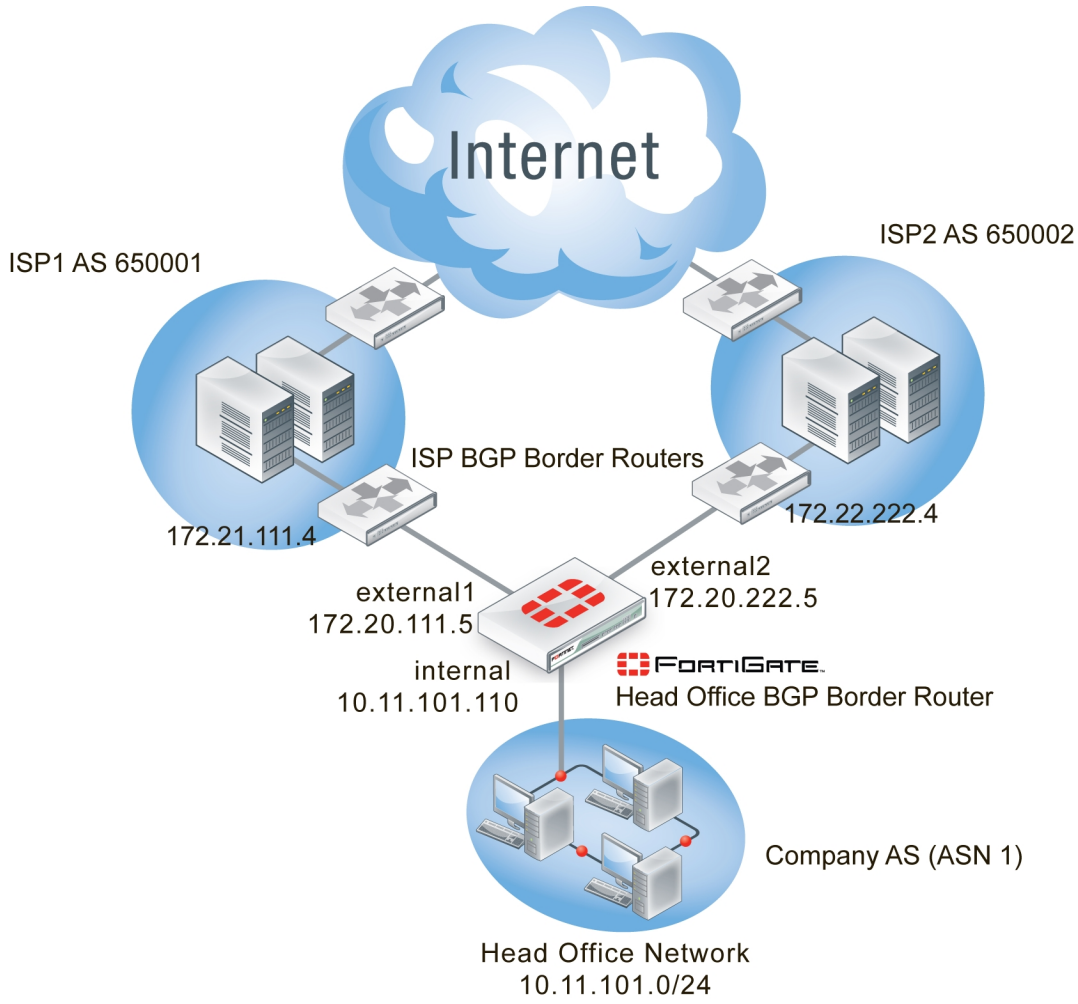
Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network — the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the Company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, an address supplied by the ISP.
- The FortiGate unit external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, an address supplied by the ISP.
- ISP1 AS has an AS number of 650001, and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.
- Apart from graceful restart, and shorter timers (holdtimer, and keepalive) default settings are to be used whenever possible.

Basic BGP network topology



Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route, and ISP2 is the secondary route
- All basic configuration can be completed in both GUI and CLI
- Only one AS is used for the Company

For these reasons this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- Changing redistribution defaults — make link when example is set up
- IPv6

For more information on these features, see the corresponding section.

Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the Company Network and the ISP network. The FortiGate unit is the only BGP router on the Company Network, but there is at least one other BGP router on the ISP Network — there may be more but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the Company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled such as graceful restart, or route dampening that should be determined up front so those features can be enabled on the FortiGate unit.

To configure the FortiGate unit as a BGP router

1. Configure interfaces and default routes
2. Configure firewall services, addresses, and policies
3. Set the FortiGate BGP information
4. Add the internal network to the AS
5. Additional FortiGate BGP configuration

Configure interfaces and default routes

The FortiGate unit is connected to three networks — Company Network on the internal interface, ISP1 Network on external1interface, and ISP2 on external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required such as setting the maximum MTU size, or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled Internal, or External. Instead, for clarity's sake, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here as well. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - web-based manager

1. Go to **System > Network > Interface**.
2. Edit port 1 (internal) interface.
3. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Company internal network
Administrative Status	Up

4. Edit port 2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP1 External BGP network
Administrative Status	Up

6. Edit port 3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP2 External BGP network
Administrative Status	Up

To configure the FortiGate interfaces - CLI

```
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.110 255.255.255.0
      set allowaccess http https ssh
      set description "Company internal network"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP1 External BGP network"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP2 External BGP network"
      set status up
   next
end
```

To configure default routes for both ISPs - web-based manager

1. Go to **Router > Static > Static Routes**.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	172.21.111.5
Distance	10

4. Select **OK**.
5. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	172.22.222.5
Distance	15

6. Select **OK**.

To configure default routes for both ISPs - CLI

```
config router static
   edit 1
      set device "port2"
      set distance 10
      set gateway 172.21.111.5
   next
   edit 2
      set device "port3"
      set distance 15
      set gateway 172.22.222.5
   next
end
```

Configure firewall services, addresses, and policies

To create the security policies, first you must create the firewall services group that will include all the services that will be allowed, then you must define the addresses that will be used in the security policies, and lastly you configure the security policies themselves.

To keep the configuration simple, the Company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web-mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example if only 20 addresses are used, only allow those addresses in the range.

In the interest of keeping things simple, a zone will be used to group the two ISP interfaces together. This will allow using one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple, and in the future if there is a need for separate policies for each ISP, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports, and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information on security policies, see the firewall chapter of the FortiGate Administration Guide.

When configuring security policies always enable logging to help you track and debug your traffic flow.

To create a firewall services group - web-based manager

1. Go to **Policy & Objects > Objects > Services**, select the dropdown arrow next to **Create New** and select **Service Group**.
2. For **Group Name**, enter “Basic_Services”.
3. From the **Members** dropdown, choose the following six services — BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4. Select **OK**.

To create a firewall services group - CLI

```
config firewall service group
   edit "Basic_Services"
      set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
   next
end
```

To create a zone for the ISP interfaces - web-based manager

1. Go to **System > Network > Interfaces.**
2. Select the caret to the right of **Create New** and then select **Zone**.
3. Enter the following information.

Zone Name	ISPs
Block Intra-zone traffic	enable
interface members	port2 port3

4. Select **OK**.

To create a zone for the ISP interfaces - CLI

```
config system zone
   edit "ISPs"
      set interface "port2" "port3"
      set intrazone block
   next
end
```

To add the firewall addresses - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	Internal_network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3. Select **OK**.

To add the firewall addresses - CLI

```
config firewall address
   edit "Internal_network"
      set associated-interface "port1"
      set subnet 10.11.101.0 255.255.255.0
   next
end
```

To add the HTTP and DNS security policies - web-based manager

1. Go to **Policy & Objects > Policy > IPv4**, and select **Create New**.
2. Set the following information.

Incoming Interface	port1(internal)
Source Address	Internal_network
Outgoing Interface	ISPs
Destination Address	All
Schedule	Always
Service	Basic_services
Action	ACCEPT

Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services out policy

3. Select **OK**.
4. Select **Create New**, and set the following information.

Incoming Interface	ISPs
Source Address	All
Outgoing Interface	port1(internal)
Destination Address	Internal_network
Schedule	Always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services in policy

To add the security policies - CLI

```
config firewall policy
   edit 1
      set srcintf "port1"
      set srcaddr "Internal_network"
      set dstintf "ISPs"
      set dstaddr "all"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
      set comments "ISP1 basic services out policy"
   next
   edit 2
      set srcintf "ISPs"
      set srcaddr "all"
      set dstintf "port1"
      set dstaddr "Internal_network"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
```

```
      set comments "ISP1 basic services in policy"
   next
end
```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbor, even that route out is not available. So while after this part of the configuration is complete your FortiGate unit will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - web-based mananger

1. Go to **Router > Dynamic > BGP**.
2. Set the following information, and select **OK**.

Local As	1
Router ID	10.11.101.110

To set the BGP router information - CLI

```
config router BGP
   set as 1
   set router-id 10.11.101.110
end
```

Add the internal network to the AS

The Company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASes. The internal network in the Company's AS must be defined. If there were other networks in the company such as regional offices, they would be added here as well.

To set the networks in the AS - web-based manager

1. Go to **Router > Dynamic > BGP**.
2. In **Networks**, next to **IP/Netmask**, set the following information and select **Add**.

IP/Netmask	10.11.101.0/255.255.255.0

To set the networks in the AS - CLI

```
config router bgp
   config network
   edit 1
      set prefix 10.11.101.0 255.255.255.0
   next
   end
end
```

Add BGP neighbor information

The configuration will not work unless you set **Remote AS** neighbors. This can be done in either the web-based manager or the CLI.

To configure the BGP neighbors - web-based manager

1. Go to **Router > Dynamic > BGP**.
2. Add a **Neighbors IP** of 172.21.111.4 with the **Remote AS** set to 650001, then click **Add/Edit**.
3. Add another **Neighbors IP** of 172.22.222.4 with the **Remote AS** set to 650002, then click **Add/Edit**.

To configure the BGP neighbors - CLI

```
config router BGP
   set as 1
      config neighbor
         edit "172.21.111.4"
            set remote-as 650001
         next
         edit "172.22.222.4"
            set remote-as 650002
         next
      end
   end
```

Additional FortiGate BGP configuration

At this point that is all the settings that can be done in both the web-based manger and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers such as keep alive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simply features are being used to promote faster detections of network failures which will result in better service for the Company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit, and where possible on neighboring routers as well:

- `bestpath-med-missing-as-worst` — treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover` — immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*` — advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands applies to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer` — how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer` — how often the router sends out keepalive messages to neighbor routers to maintain those sessions.

- `log-neighbor-changes` — log changes to neighbor routers' status. This can be useful for troubleshooting from both internal and external networks.
- `connect-timer` — how long in seconds the FortiGate unit will try to reach this neighbor before declaring it offline.
- `weight` — used to prefer routes from one neighbor over the other. In this example ISP1 is the primary connection so it is weighted higher than ISP2

To configure additional BGP options - CLI

```
config router bgp
   set bestpath-med-missing-as-worst enable
   set fast-external-failover enable
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
   set graceful-update-delay 180
   set holdtime-timer 120
   set keepalive-timer 45
   set log-neighbor-changes enable
   config neighbor
      edit 172.21.111.4
         set connect-timer 60
         set description "ISP1"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 250
      next
      edit 172.22.222.4
         set connect-timer 60
         set description "ISP2"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 100
      next
   end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured: both ISPs' BGP routers.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2 that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- The router ID
- Your Company's AS number

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm things are working as expected.

In general for routing you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in two parts:

- Testing network connectivity
- Verifying the FortiGate unit's routing tables
- Verifying traffic routing
- Verifying the dual-homed side of the configuration

Testing network connectivity

A common first step in testing a new network topology is to test if you can reach the Internet and other locations as you expect you should. If not, you may be prevented be cabling issues, software or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit's interfaces and ISP routers have ping support enabled. Also ensure that the security policies allow ping through the firewall.

Connections to test in this example are the internal network to ISP1's router or the Internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. Those three tests should prove your basic network connections are working.

Once you have completed testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate unit's routing tables

The FortiGate routing table contains the routes stored for future use. If you are expecting certain routes to be there and they are not, that is a good indicator that your configuration is not what you expected.

The CLI command `get router info routing-table details` will provide you with every route's routing protocol, destination address, gateway address, interface, weighting, and if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the CLI command `get router info routing-table bgp`. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command you can replace BGP with static, or other routing protocols to only display those routes.

If you want to see the contents of the routing information database (RIB), use the CLI command `get router info routing-table database`. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try and access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the Internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer other other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- Default static routes — If these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information — If the ISP router information is incorrect, the FortiGate unit won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best to not advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way, or some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your Company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example the Company has an internal network in an OSPF area, and is connected to a BGP AS and two BGP peers. Company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The Company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Testing network configuration

Network layout and assumptions

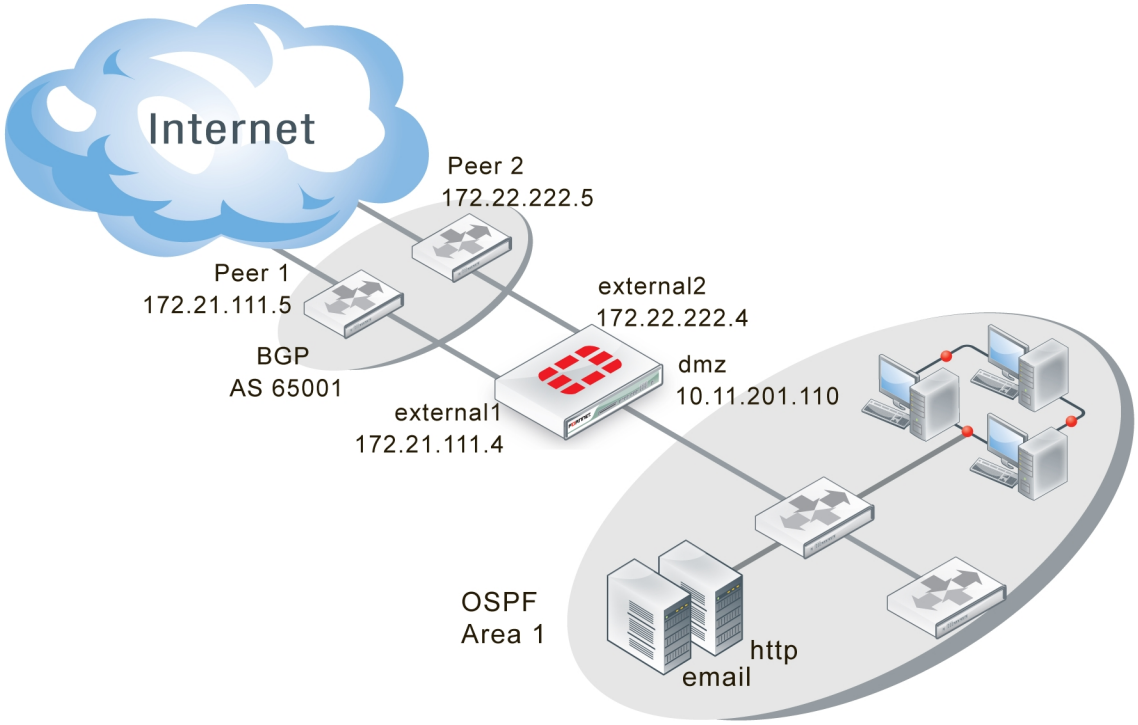
The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example — AS 65001, shared by the FortiGate unit and both peers.
- The Company's FortiGate unit connects to the Internet through two BGP peers.

- The Company internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate units' interfaces are connected as follows:
  - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
  - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
  - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

BGP network topology



Assumptions

The the BGP redistributing routes configuration procedure follows these assumptions:

- The FortiGate unit has been configured following the Install Guide
- Interfaces port1, port2, and port 3 exist on the FortiGate unit
- We don't know the router manufacturers of Peer 1 and Peer 2
- We don't know what other devices are on the BGP AS or OSPF Area
- All basic configuration can be completed in both GUI and CLI
- Access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

Configuring the FortiGate unit

1. Configuring the FortiGate unit — networks and firewalls
2. Configuring the FortiGate unit - BGP
3. Configuring the FortiGate unit - OSPF
4. Configuring other networking devices
5. Configuring ECMP support for BGP

Configuring the FortiGate unit — networks and firewalls

The FortiGate unit has three interfaces connected to networks — two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network — either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web-server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). Those last two can be removed once the network is up and working properly to increase security. Other services can be added later as needed.

To configure the interfaces - GUI

1. Go to **System > Network > Interfaces**.
2. Edit port1 (dmz) interface.
3. Set the following information, and select **OK**.

Alias	dmz
IP/Network Mask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4. Edit port2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external Peer 1
Administrative Status	Up

6. Edit port3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces (CLI)

```
config system interface
   edit port1
      set alias dmz
      set ip 10.11.201.110 255.255.255.0
      set allowaccess https ssh ping
      set description "OSPF internal networks"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "external1 Peer 1"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "external2 Peer 2"
      set status up
   next
end
```

To configure the firewall addresses - GUI

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	BGP_services
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select **OK**.

To configure the firewall addresses - CLI

```
config firewall address
   edit "BGP_services"
      set associated-interface "port1"
      set subnet 10.11.201.0 255.255.255.0
   next
end
```

To configure firewall service groups - GUI

1. Go to **Policy & Objects > Objects > Services.** Under the **Create New** dropdown menu, select **Service Group**.
2. Name the group BGP_Services.
3. Add the following services to the **Members** list: BGP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
4. Select **OK**.
5. Create another new **Service Group**.
6. Name the group OSPF_Services.
7. Add the following services to the *Members* list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
8. Select **OK**.

To configure firewall service groups - CLI

```
config firewall service group
   edit "BGP_services"
      set member "BGP", "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP"
          "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG"
   next
   edit "OSPF_services"
      set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP" "MYSQL"
          "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG" "OSPF"
   next
end
```

Configuring the FortiGate unit - BGP

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1's routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it makes no sense to advertise unneeded routes.

Blocking Peer 1's routes to Peer 2 is done with distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI

```
config access-list
   edit "block_peer1"
```

```
      config rule
      edit 1
         set prefix 172.21.111.0 255.255.255.0
         set action deny
         set exact-match enable
      end
   end
end
```

To configure BGP on the FortiGate unit - CLI

```
config router bgp
   set as 65001
      set router-id 10.11.201.110
      config redistribute ospf
         set status enable
      end
      config neighbor
      edit 172.22.222.5
         set remote-as 65001
         set distribute-list-out "block_peer1"
      next
      edit 172.21.111.5
         set remote-as 65001
      end
   end
```

Configuring the FortiGate unit - OSPF

This configuration involves only one OSPF Area, so all traffic will be intra-area. If there were two or more areas with traffic going between them it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBPG). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. For Router ID enter `10.11.201.110` and then select **Apply**.
3. Under **Advanced Options** > **Redistribute**, select **BGP** and set the BGP **Metric** to 1.
4. For **Areas**, select **Create New,** enter the following information and then select **OK**.

Area (IP)	`0.0.0.0`
Type	Regular
Authentication	None

5. For **Networks**, select **Create New**.
6. Enter 10.11.201.0/255.255.255.0 for **IP/Netmask**, and select **OK**.
7. For **Interfaces**, select **Create New**.

8. Enter `OSPF_dmz_network` for **Name**.
9. Select `port1(dmz)` for **Interface**, and then select **OK**.

To configure OSPF on the FortiGate unit - CLI

```
config router ospf
   set router-id 10.11.201.110
   config area
      edit 0.0.0.0
         set type regular
         set authentication none
      end
   config network
      edit 1
         set area 0.0.0.0
         set prefix 10.11.201.0 255.255.255.0
      end
   config interface
      edit "OSPF_dmz_network"
         set interface port1(dmz)
         set status enable
      end
   config redistribute bgp
      set status enable
      set metric 1
   end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information including IP address, AS number, and what capabilities are being used such as IPv6, graceful restart, BFD, and so on.

Configuring ECMP support for BGP

"ECMP" stands for "Equal Cost Multiple Path". ECMP is a mechanism that allows multiple routes to the same destination with different next-hops and load-balances routed traffic over those multiple next-hops.

- ECMP only works for routes that are sourced by the same routing protocol (that is: Static Routes, OSPF, or BGP).
- ECMP is enabled by default with 10 paths.
- ECMP with static routes is effective if the routes are configured with the same distance and same priority.

To configure ECMP support - CLI

```
config router bgp
   set ebgp-multipath disable[|enable]
   set ibgp-multipath disable[|enable]
   ...
end
```

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensuring that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see Redistributing and blocking routes in BGP on page 363.

Open Shortest Path First (OSPF)

This section describes OSPF routing.

The following topics are included in this section:

OSPF Background and concepts
Troubleshooting OSPF
Basic OSPF example
Advanced inter-area OSPF example
Controlling redundant links by cost

OSPF Background and concepts

OSPF (Open Shortest Path First) is a link-state interior routing protocol, that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP as BGP can communicate between ASes.

This section includes:

- Background
- The parts and terminology of OSPF
- How OSPF works

Background

OSPF version 2 was defined in 1998 in RFC 2328. OSPF was designed to support classless IP addressing, and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPF version 2 are included in OSPF version 3 defined in 2008 in RFC 5340. OSPF3 includes support for IPv6 addressing where previously OSPF2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds has converged network traffic successfully without any networking loops. Also OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

The parts and terminology of OSPF

Parts and terminology of OSPF includes:

- OSPFv3 and IPv6
- Router ID
- Adjacency
- Designated router (DR) and backup router (BDR)
- Area
- Authentication
- Hello and dead intervals
- Access Lists

OSPFv3 and IPv6

OSPFv3 (OSPF version 3) includes support for IPv6. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in RFC 2740. Likewise, the router ID and area ID are in the same format as OSPFv2.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Config > Features**.

For IPv6, the main difference in OSPFv3 is that, rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
   config area
      edit 0.0.0.0
   next
end
config ospf6-interface
   edit "tunnel"
   set interface "to_FGT300A-7"
next
   edit "internal_lan"
   set interface "port1"
next
   set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

Router ID

In OSPF, each router has a unique 32-bit number called its Router ID. Often this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea to not use IP address in use on the router for the router ID number. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused which number you are looking at. A good idea can be to use the as much of the area's number as possible. For example if you have 15 routers in area 0.0.0.0 they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10 for example.

You can manually set the router ID on your FortiGate unit.

To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. For **Router ID**, enter `0.0.1.1`.
3. Select **Apply**.

To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
   set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, when an OSPF router boots up it sends out OSPF Hello packets to find any neighbors, routers that have access to the same network as the router booting up. Once neighbors are discovered and Hello packets are exchanged, updates are sent, and the Link State databases of both neighbors are synchronized. At this point these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met.

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The Hello interval & The Dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

Adjacency and neighbors

Neighbor routers can be in a Two-Way state, and not be adjacent. Adjacent routers normally have a neighbor state of FULL. Neighbors only exchange Hello packets, and do not exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as Hello packets. A good example of an adjacent pair of routers is the DR and BDR.

You can check on the state of an OSPF neighbor using the CLI command `get router info ospf neighbor all`. See OSPF Background and concepts on page 371.

Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes.

If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates it would flood the network.

Also, it is better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent.

The BDR also has this information in case the DR goes offline.

Designated router (DR) and backup router (BDR)

In OSPF a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all the initial contact and other routing administration traffic. Having only one router do all this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link-state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may only have a couple routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic but to a lesser extent than on a large network. Also, your network topology will be ready whenever you choose to expand your network.

DR and BDR election

An election chooses the DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers—the highest priority becomes the DR, and the second highest becomes BDR. To resolve any ties, the router with the highest router ID wins. For example 192.168.0.1 would win over 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes on line after the election, it must wait until after the DR and BDR go offline before it would become the DR.

If the original DR goes offline, but then is available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF designated router or backup designed router called `ospf_DR` on the network, you need to raise the priority of the router to a very high number such as 250 out of 255. This will ensure the router has a chance to be a DR, but will not guarantee that it will be one. Give the FortiGate a high router ID—such as 192.168.1.1 instead of 10.1.1.1—to help ensure it becomes a DR, but that is not part of this example. Enter the following command:

```
config router ospf
   config ospf-interface
   edit "ospf_DR"
      set priority 250
   end
end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link-state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

Within an area if there are two or more routers that are viable, there will always be a designated router (DR) and a backup DR (BDR). For more on these router roles, see Designated router (DR) and backup router (BDR) on page 374.

Defining a private OSPF area, involves:

- Assigning a 32-bit number to the area that is unique on your network
- Defining the characteristics of one or more OSPF areas
- Creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- If required, adjusting the settings of OSPF-enabled interfaces.

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF area:

- Backbone area
- Stub area
- NSSA
- Regular area

Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, or possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason the backbone not only has to connect to all other areas in the network, but also be uninterrupted to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it, and all routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or there are other reasons to prevent outside traffic, such as security. For example most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to only using he default route for internal routing.

Regular area

A regular area is what all the other ASes are, all the non-backbone, non-stub, non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

Authentication

In the OSPF packet header are two authentication related fields —AuType, and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there is no authentication being used. In this case the 16-byte Authentication field is not checked, and can be any value. However checksumming is still used to locate errors. On your FortiGate this is the `none` option for authentication.

Simple Password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use of this type of authentication is to prevent routers from accidently joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear—a packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of “ospf_test”, enter the command:

```
config router ospf
   config ospf-interface
   edit Accounting
      set interface port1
      set network-type broadcast
```

```
      set hello-interval 10
      set dead-interval 40
      set authentication text
      set authentication-key "ospf_test"
   end
end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the Hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out Hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a Hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time other routers will wait before declaring a neighbor dead (offline). Setting a reasonable dead interval is very important. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link-state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic.

FortiOS also supports OSPF fast-hello, which provides a way of sending multiple Hello packets per second. This is achieved by setting a dead-interval to one second. The hello-multiplier, which can be any number between 4 and 10, determines the number of Hello packets that will be sent every second. The CLI syntax for OSPF fast-hello follows:

```
config ospf-interface
   edit ospf1
      set interface port1
      set network-type broadcast
      set dead-interval 1
      set hello-multiplier 4
end
```

Access Lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also, it eases troubleshooting since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
   edit test_list
   config rule
      edit 1
         set prefix 10.10.10.10 255.255.255.255
         set action allow
         set exact-match enable
      next
      edit 2
         set prefix 11.11.11.11 255.255.255.255
         set action allow
         set exact-match enable
      end
   end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following command:

```
config router ospf
   config distribute-list
      edit 5
         set access-list test_list
         set protocol connected
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers. A group of contiguous networks form an area. An Area Border Router (ABR) links one or more areas to the OSPF network backbone (area ID 0). See Dynamic Routing Overview on page 279.

OSPF is an interior routing protocol. It includes a backbone AS, and possibly additional ASes. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that is uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP, or BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works includes:

- OSPF router discovery
- How OSPF works on FortiGate units
- External routes
- Link-state Database (LSDB) and route updates
- OSPF packets

OSPF router discovery

OSPF-enabled routers generate Link-State Advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the follow steps occur.

1. When OSPF routers come online, they send out Hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, generally they become adjacent. Adjacent routers can exchange routing updates. See Adjacency on page 373.
3. A DR and BDR are elected from the available routers using priority settings, and router ID. See Designated router (DR) and backup router (BDR) on page 374, and OSPF Background and concepts on page 371.
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF Hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit, and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges Hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, used for OSPF E1 and OSPF E2.

OSPF external1 (E1)

In OSPF E1 the destination is outside of the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF external2 (E2)

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, on border routers that have no OSPF portion for example or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost - essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through your CLI.

To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes including the OSPF external routes, or for a shorter list you can use the command `get router info routing-table ospf`. The letter at the left will be either E1 or E2 for external OSPF routes. The output of will look similar to the following, depending on what routes are in your routing table.

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link-state Database (LSDB) and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with Link-state database (LSDB) updates. External links allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link-state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link-state updates passed along the network. When there are no more changes required, and the network is stable then the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link-state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path, how fast traffic will get from one point to another.

The path cost, similar to "distance" for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding together all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas (RFC 3509).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- The addresses of networks in the local OSPF area (to which packets are sent directly)
- Routes to OSPF area border routers (to which packets destined for another area are sent)
- If the network contains OSPF areas and non-OSPF domains, routes to area boundary routers, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF Route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

Our router gets a new route, and needs to decide if it should go in the routing table.

The router has an up to date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.

Our router, turns the LSDB into a shortest path first (SPF) tree using Dijkstra's algorithm. It doesn't matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

Once the SPF tree has been created, and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.

If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can update their LSDBs as well. This is vital since all routers on the OSPF area must have the same LSDB.

If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-byte Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields.

Version field — The OSPF version number. This specification documents version 2 of the protocol.

Type field — There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length — The length of the OSPF protocol packet in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID — The Router ID of the packet's source.

Area ID — A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum — The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure; for some authentication types the checksum calculation is omitted.

Auth Type — Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication — A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the Authentication fields is not checked and can be any value. When AuType is set to 2 (Cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The authentication data length field indicates how many bytes long the message digest is, and the cryptographic sequence number is at non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask — The subnet where this packet is valid.

Hello interval — The period of time between sending out Hello packets. See Hello and dead intervals on page 377.

Options field — The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF Hello packets, Database Description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single Autonomous System.

Router priority — The priority between 0 and 255 that determines which routers become the DR and BDR. See Designated router (DR) and backup router (BDR) on page 374.

Dead router interval — The period of time when there is no response from a router before it is declared dead. See Hello and dead intervals on page 377.

DR and BDR fields — The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. See Designated router (DR) and backup router (BDR) on page 374.

Neighbor ID — The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the FortiOS Handbook Troubleshooting chapter.

The more common issues include:

- Clearing OSPF routes from the routing table
- Checking the state of OSPF neighbors
- Passive interface problems
- Timer problems
- Bi-directional Forwarding Detection (BFD)
- Authentication issues
- DR and BDR election issues

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` command. The exec router clear command is much more limiting for OSPF than it is for BGP. See Border Gateway Protocol (BGP) on page 332.

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

```
execute router clear ospf process
```

Checking the state of OSPF neighbors

In OSPF each router sends out link state advertisements to find other routers on its network segment, and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI command `get router info ospf neighbor all` to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State    Dead Time Address Interface
10.0.0.2     1    Full/ -  00:00:39 10.1.1.2 tunnel_wan1
10.0.0.2     1    Full/ -  00:00:34 10.1.1.4 tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link-state table.

Passive interfaces can cause problems when they aren't receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out-of-date link-state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device and allow it to repopulate the table.

If you cannot make the interface active for some reason, you will have to change your network to fix the "hole" by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example if one router declares a router dead after 45 seconds and another waits for 4 minutes that difference in time will result in those two routers being out of synch for that period of time—one will still see that offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval, and dead interval periods, so you can compare them easily enough.

Bi-directional Forwarding Detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing - they won't acknowledge a router. This can be a problem if that router connects areas to the backbone as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets, and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. Its possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems—it may only be one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is authentication related, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting their priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all that traffic.

However, if you set all the other routers to not have a chance at being elected, a priority of zero, you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. But if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or the other tasks the DR performs.

The solution to this is to always allow routers to have a chance at being promoted, even if you set their priority to one. In that case they would be the last choice, but if there are no other candidates you want that router to become the DR. Most networks would have already alerted you to the equipment problems, so this would be a temporary measure to keep the network traffic moving until you can find and fix the problem to get the real DR back online.

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPF v2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and router2 will be the backup DR (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections.

Instead, Router3 is the area border router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow, and is charged by the amount of traffic. For these reasons OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. The ISP network does have to be added to that router's configuration however.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are three FortiGate units acting as OSPF v2 routers on the network—Router1, Router2, and Router3. Router1 will be the designated router (DR), and Router 2 the BDR. Router3 is the area border router (ASBR) that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The Head Office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

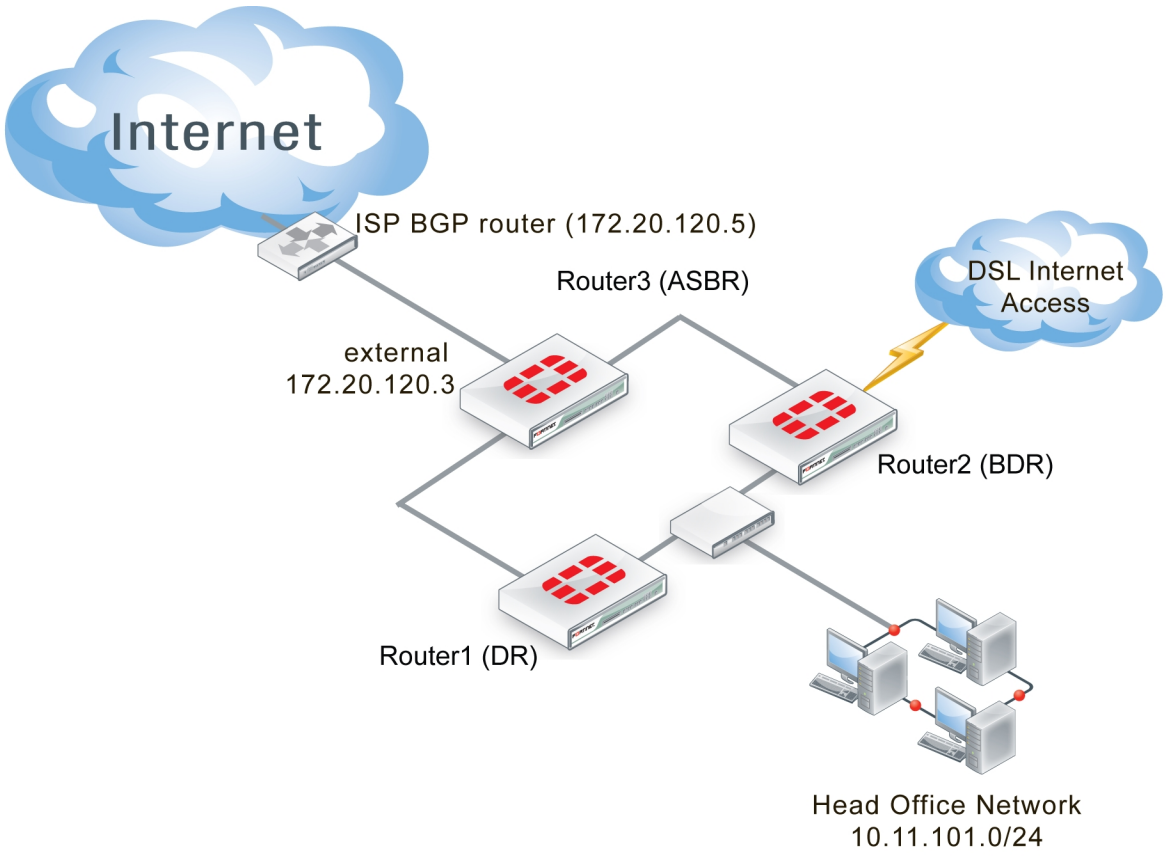
Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

Routers, interfaces, and IP addresses for basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network, and Router2
	External (port2)	10.11.102.1	Router3
Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network, and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
	Internal1 (port1)	10.11.102.3	Router1
Router3 (ASBR)	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Basic OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 5.2 firmware installed, and are in NAT/Route operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

Configuring the FortiGate units

Each FortiGate unit needs the interfaces, and basic system information such as hostname configured.

This section includes:

- Configuring Router1
- Configuring Router2

- Configuring Router3

Configuring Router1

Router1 has two interfaces connected to the network—internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **System > Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway will be retrieved from the ISP, and the defaults will be used for the rest of the PPPoE settings.

To configure Router2 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **System > Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6. Edit DSL (port3), set the following information, and select **OK**.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network which has no administration access enabled for security reasons.

To configure Router3 interfaces - web-based manager

1. Go to **System > Status > Dashboard**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **System > Network > Interfaces, e**dit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	Internal2
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information, and select **OK**.

Alias	External
IP/Network Mask	172.20.120.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- Router ID
- Area
- Network

- Two or three interfaces depending on the router
- Priority for DR (Router1) and BDR (Router2)
- Redistribute for ASBR (Router3)

This section includes:

- Configuring OSPF on Router1
- Configuring OSPF on Router2
- Configuring OSPF on Router3

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point. Otherwise it is a standard OSPF configuration. Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

To configure OSPF on Router1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.1` and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router1-Internal-DR
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router1-External
Interface		port2 (External)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
   config ospf-interface
      edit Router1-Internal-DR
         set priority 255
      end
```

To configure OSPF on Router1 - CLI

```
config router ospf
   set router-id 10.11.101.1
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.255.0
      next
   end
   config ospf-interface
      edit "Router1-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router1-External"
         set interface "port2"
      next
   end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area, and configures the DSL interface slightly differently—assume this will be a slower connection resulting in the need for longer timers, and a higher cost for this route.

Otherwise it is a standard OSPF configuration.

To configure OSPF on Router2 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Router2-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name		Router2-DSL
Interface		port3 (DSL)
IP		0.0.0.0
Authentication		none
Cost		50
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
   config ospf-interface
      edit Router2-Internal
         set priority 250
      next
   end
```

To configure OSPF on Router2 - CLI

```
config router ospf
   set router-id 10.11.101.2
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.0.0
      next
   end
   config ospf-interface
      edit "Router2-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router2-External"
         set interface "port2"
      next
      edit "Router2-DSL"
         set interface "port3"
         set cost 50
      next
   end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 a border router or ASBR. Also Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, Redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. Expand **Advanced Options**.
4. In **Redistribute**, set the following information, and select **OK**.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	

	Hello Interval	10
	Dead Interval	40

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router3-Internal2
Interface		port2 (Internal2)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router3-ISP-BGP
Interface		port3 (ISP-BGP)
IP		0.0.0.0
Authentication		none
Cost		2
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
   config ospf-interface
   edit Router3-Internal
      set priority 250
   next
end
```

To configure OSPF on Router3 - CLI

```
config router ospf
   set router-id 10.11.102.3
   config area
      edit 0.0.0.0
      next
   end
```

```
    config network
       edit 1
          set prefix 10.11.0.0/255.255.255.0
       next
       edit 2
          set prefix 172.20.120.0/255.255.255.0
       next
    end
    config ospf-interface
       edit "Router3-Internal"
          set interface "port1"
          set priority 255
       next
       edit "Router3-External"
          set interface "port2"
       next
       edit "Router3-ISP-BGP"
          set interface "port3"
          set cost 2
       next
    end
end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified of the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity, and testing the OSPF routing.

To test the network connectivity use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in Basic OSPF example on page 385.

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas would not be this small, and if they were the areas would be combined into one bigger area. However, the stub area services the accounting department which is very sensitive about their network and do not want any of their network information broadcast through the rest of the company. The backbone area contains the bulk of the company network devices. The regular area was established for various reasons such as hosting the company servers on a separate area with extra security.

One area is a small stub area that has no independent Internet connection, and only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use

that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

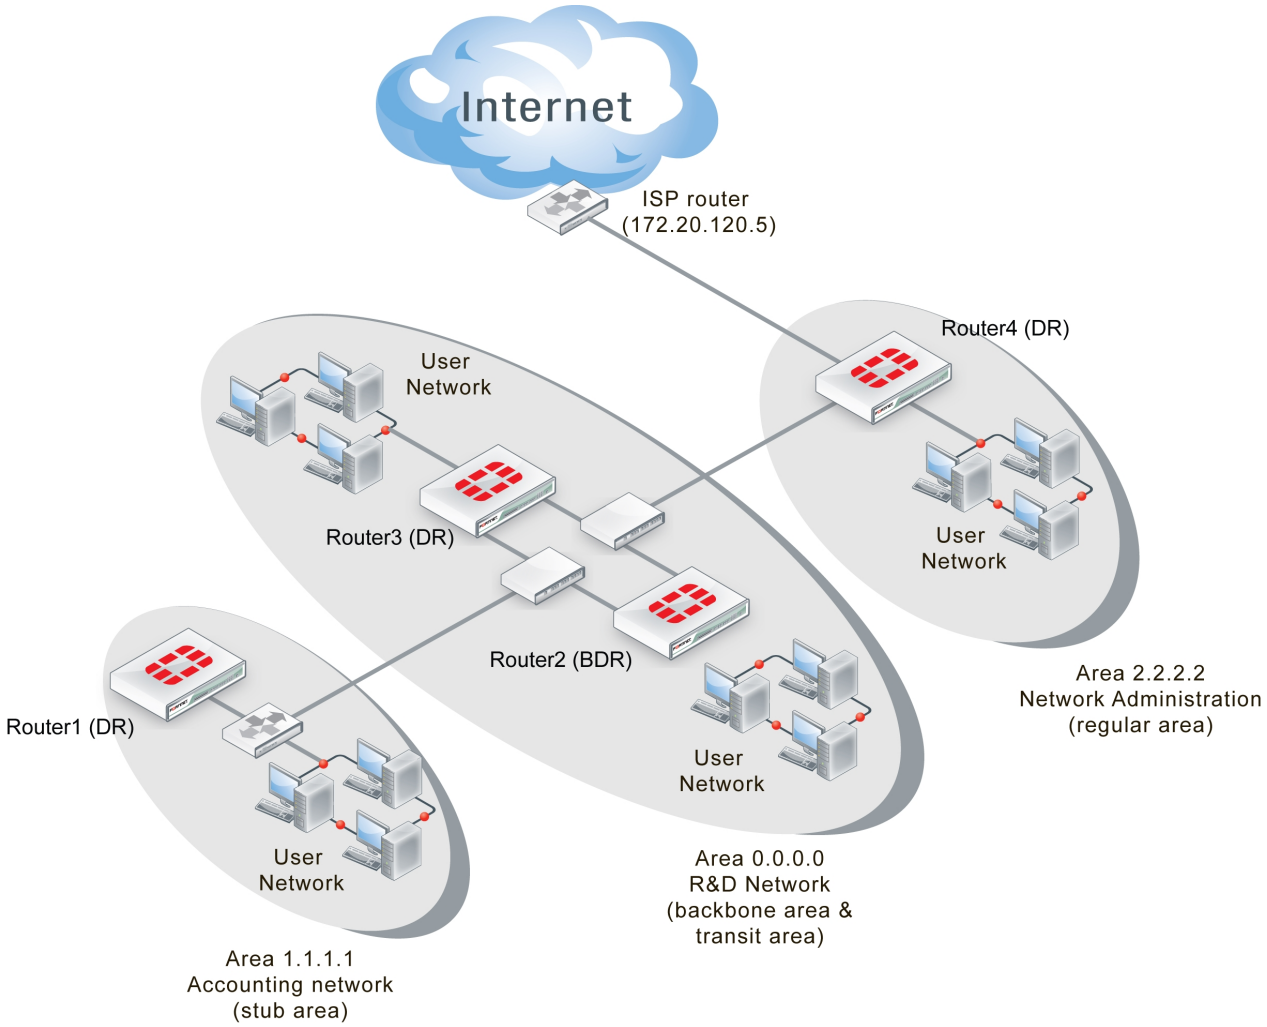
This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are four FortiGate units in this network topology acting as OSPF routers:

Advanced inter-area OSPF network topology



Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area, and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected, but they are not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Routers, areas, interfaces, IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1
Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 5.2 firmware installed, and are in NAT/Route operation mode.
- During configuration, if settings are not directly referred to they will be left at default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network, but do not affect this configuration.

Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers. These configurations include multiple interface settings, and hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only router3 (the DR) configuration will be given with notes indicating router2 (the BDR) IP addresses.

Configuring the FortiGate units includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3
- Configuring Router4

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

To configure Router1 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **System > Network > Interfaces,** edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External1
IP/Network Mask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone network and Internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured; one to the internal network, and two to Router3 for redundancy.

To configure Router2 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **System > Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.2/255.255.255.0

Administrative Access	HTTPS SSH PING
Description	Router3 second connection
Administrative Status	Up

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

To configure Router3 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **System > Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides Internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router4`, and select **OK**.
4. Go to **System > Network > Interfaces**.
5. Edit port1 (internal).
6. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

7. Edit port2 (external2).
8. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

9. Edit port3 (ISP).
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also each area needs to be configured as each respective type of area - stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter `10.11.101.1` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	1.1.1.1
Type	Stub
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Accounting
Interface	port1 (internal)
IP	10.11.101.1
Authentication	None

6. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter `10.11.102.2` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)

IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter `10.11.103.3` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New, s**et the following information, and then select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)

IP	10.11.110.3
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter `10.11.104.4` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New**.
4. Set the following information, and select **OK**.

Area	2.2.2.2
Type	Regular
Authentication	None

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Network Admin network

Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

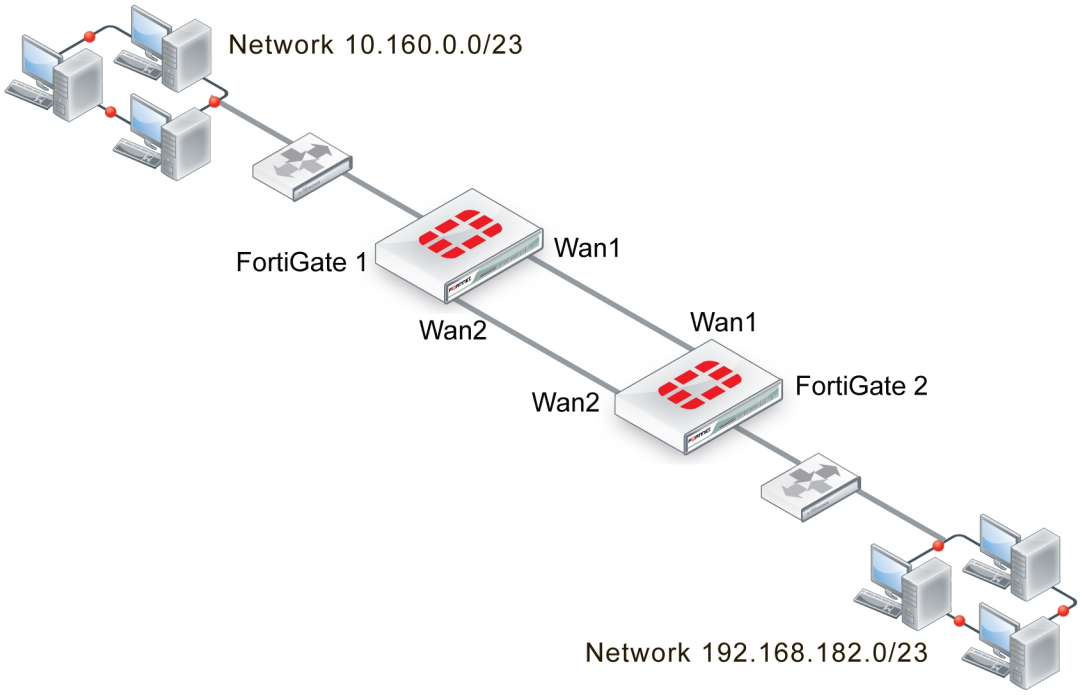
There are two main areas to test in this network configuration; network connectivity, and OSPF routing.

To test the network connectivity, see if computers on the Accounting or R&D networks can access the Internet. If you need to troubleshoot network connectivity, see the FortiOS Handbook Troubleshooting chapter.

To test the OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see Advanced inter-area OSPF example on page 397.

Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.



FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate units:

```
config router ospf
   config ospf-interface
      edit "WAN2_higher_cost"
         set cost 200
         set interface "wan2"
      end
```

Now both FortiGate units use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)

   (Link Data) Router Interface address: 10.182.0.187
   Number of TOS metrics: 0
   TOS 0 Metric: 10
```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

Intermediate System to Intermediate System Protocol (IS-IS)

This section describes the Intermediate System to Intermediate System Protocol (IS-IS).

The following topics are included in this section:

IS-IS background and concepts
How IS-IS works
Troubleshooting IS-IS
Simple IS-IS example
Network layout and assumptions
Expectations
CLI configuration
Verification
Troubleshooting

IS-IS background and concepts

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes).

Background

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see RFC 1142—note this RFC is different from the ISO version). At roughly the same time, the Internet Engineering Task Force developed OSPF (see Open Shortest Path First (OSPF) on page 371). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see RFC 1195). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware. It is quick to configure, and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful. IS-IS uses Djikstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

The FortiGate implementation supports IS-IS for IPv4 (see RFCs 1142 and 1162), but does not support IS-IS for IPv6 (although this technically can be achieved using the ZebOS routing module).

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it is straightforward to configure IS-IS on FortiGate units.

From RFC 1142:

> *The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm. Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.*

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence—static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so it is neither a strength nor a weakness.

TLV

IS-IS uses *type-length-variable (TLV)* parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and "L" octets of Value (V). They are included in all of the IS-IS Packet types. For a complete breakdown of the LSP, see LSP structure on page 413.

In IS-IS, TLVs are used to determine route-leaking and authentication, and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, see Default routing on page 416.
- To determine which TLVs are responsible for authentication, see Authentication on page 417.

For a complete list of reserved TLV codepoints, refer to RFC 3359.

LSP structure

It is difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriatey.

This section provides information on the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

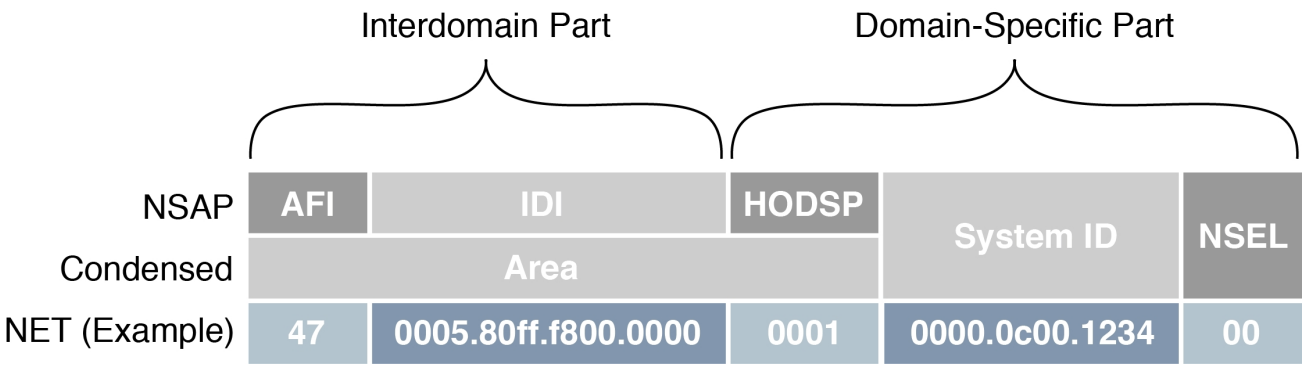
NSAP and NET

IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAPs). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the *n-selector* (NSEL). In order for adjacencies to form in IS-IS, the NSEL must necessarily be set to zero, to indicate “this system”. The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below.

NSAP and NET example



AFI — The *Authority and Format Identifier (AFI)* specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.

IDI — The *Initial Domain Identifier (IDI)* identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you do not need to specify an IDI, since the network is private.

HODSP — The *High Order Domain-Specific Part (HODSP)* identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.

System ID — The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.

NSEL — The *n-selector (NSEL)*, as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

This section includes:

- DIS election and pseudonode LSP
- Packet types
- Default routing
- Timer options
- Authentication

DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure, and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSD) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

Intermediate System-to-Intermediate System Hello (IIH) PDU — As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS.

Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies.

The DIS typically floods Hello packets to the entire LAN every three seconds.

Link-state PDU (LSP) — The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), then out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated.

For a more detailed breakdown of the LSP, see LSP structure on page 413.

Complete sequence number PDU (CSNP) — CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge.

In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbors. In other words, they are never flooded.

Partial sequence number PDU (PSNP) — PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

Default routing

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to **Router > Monitor > Routing Monitor**.

Route leaking

Route leaking is the term used to describe the bi-directional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to leak Level 2 routing information into a Level 1 area, you must configure an export policy. Whether or not a route is leaked is determined by the ATT bit, using TLV 128 (for internal IP reachability) and TLV 130 (for external IP address information). For more information on TLVs, see Troubleshooting IS-IS on page 418.

To configure IS-IS route leaking, use the following CLI commands.

1. On a Level 1-2 router:

```
config router isis
   set redistribute-l2 enable
end
```

2. On a Level 1 router:

```
config router isis
   get router info routing-table isis
   get router info isis route
end
```

Default information originate option

Enabling default-information-originate generates and advertises a default route into the FortiGate unit's IS-IS-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. IS-IS does not create the default route unless you use the `always` option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into IS-IS updates.

The CLI commands associated with default information originate include:

```
config router isis
   set default-originate
end
```

Timer options

IS-IS uses various timers to regulate its performance including a garbage timer, update timer, and timeout timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations—if you change these settings, ensure that the new settings are compatible with local routers and access servers.

You can configure the three IS-IS timers in the CLI, using the following commands:

```
config router isis
   set garbage-timer
   set update-timer
   set timeout-timer
end
```

You will find more information on each timer below.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the DIS is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication

In routing protocols, it is typically desireable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information on TLVs, see TLV on page 413.

Initially, IS-IS used plain Clear Text to navigate the authentication rules, but this was found to be insecure since the Clear Text packets were unencrypted and could be exposed to packet sniffers. As per RFC 3567, HMAC-MD5 and Enhanced Clear Text authentication features were introduced to IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain Clear Text authentication.

HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From RFC 2085:

> *The "AH Key" is used as a shared secret between two communicating parties. The Key is not a "cryptographic key" as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed."*

Clear Text authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from Clear Text authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities do not compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

Enhanced Clear Text authentication

Enhanced Clear Text authentication is an extension to Clear Text authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authentican key chain, and allows for more simple password modification and password management. Enhanced Clear Text authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, then the PDU is automatically discarded.

From RFC 5310:

> *It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.*

Troubleshooting IS-IS

This section includes:

- Routing loops
- Split horizon and Poison reverse updates

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Checking your logs
- Using SNMP network monitoring
- Using Link Health Monitor and e-mail alerts
- Looking at the packet flow

If you aren’t running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report > Log & Archive Access**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > Config > SNMP**.
2. Enable **SNMP Agent**.
3. Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
4. In either **SNMP v1/v2c** section or **SNMP v3** section, as appropriate, select **Create New**.
5. Enter the **Community Name** that you want to use.
6. In **Hosts**, select Add to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In **SNMP Event**, select the events you want to be notified of. For routing loops this should include **CPU Overusage**, **Memory Low**, and possibly **Log disk space low**. If there are problems, the log will be filling up quickly, and the FortiGate unit's resources will be overused.
9. Select **OK**.
10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Using Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful for dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor

1. To configure dead gateway detection, go to **Router > Static > Settings** and select **Create New**.
2. Set the **Probe Interval** (how often to send a ping), and **Failure Threshold** (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.
3. You may also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email to the outage.

Looking at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet; one of these routers uses OSPF and the other uses RIP.

Your task is to configure the four FortiGates to route traffic and process network updates using IS-IS, such that the farthest FortiGate (see 'FGT4' in Network layout and assumptions on page 422) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

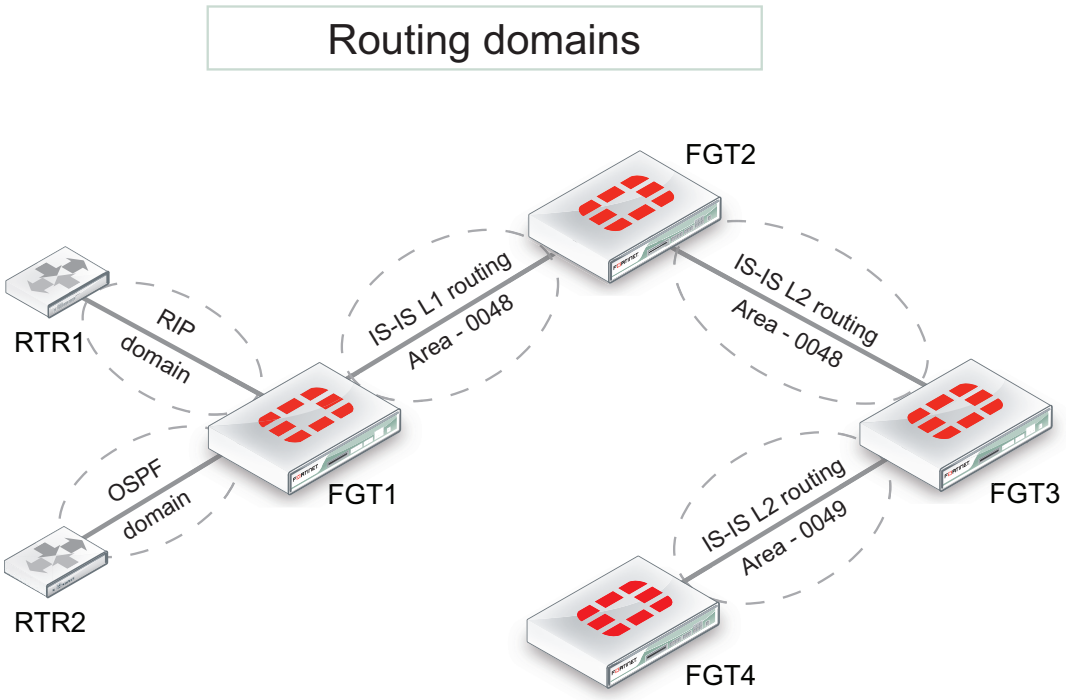
Since the internal networks use OSPF and RIP, those protocols will need to be redistributed through the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

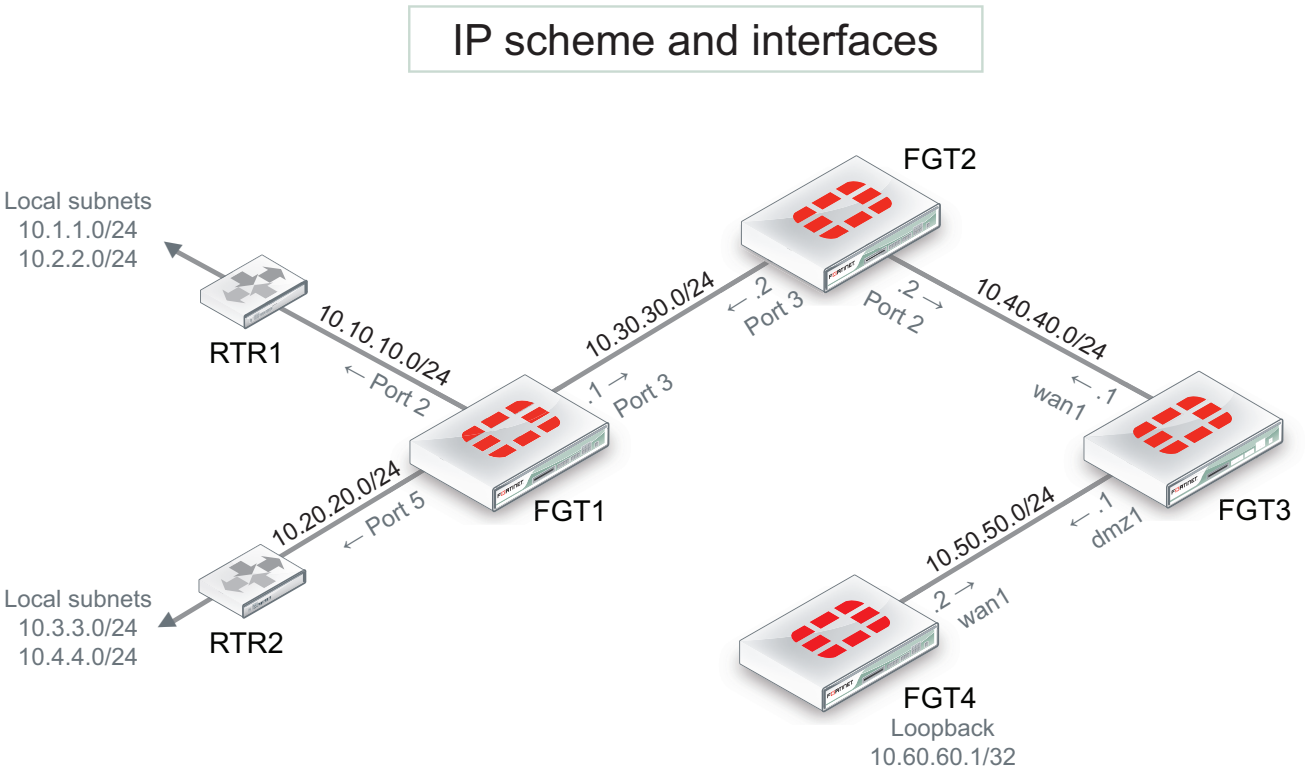
With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

This section includes the following topics:

- Network layout and assumptions
- Expectations
- CLI configuration
- Verification
- Troubleshooting

Network layout and assumptions





- It is assumed that each FortiGate is operating in NAT mode, running FortiOS 5.2.
- All interfaces have been previously assigned and no static routes are required.
- The AFI (Authority and Format Identifier) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

FGT1

```
config router isis
   config isis-interface
      edit "port3"
         set circuit-type level-1
         set network-type broadcast
         set status enable
      next
   end
   config isis-net
      edit 1
         set net 49.0048.1921.6818.2136.00
      next
```

```
      end
      config redistribute "connected"
      end
      config redistribute "rip"
         set status enable
         set level level-1
      end
      config redistribute "ospf"
         set status enable
         set level level-1
      end
   end
   config router rip
      config interface
         edit "port2"
            set receive-version 2
            set send-version 2
         next
      end
      config network
         edit 1
            set prefix 10.10.10.0 255.255.255.0
         next
      end
      config redistribute "isis"
         set status enable
      end
   end
```

FGT2

```
   config router isis
      config isis-interface
         edit "port3"
            set circuit-type level-1
            set network-type broadcast
            set status enable
         next
         edit "port2"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0048.1221.6818.2110.00
         next
      end
      set redistribute-l1 enable
      set redistribute-l2 enable
   end
```

FGT3

```
   config router isis
```

```
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
         edit "dmz1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0048.1921.6818.2108.00
         next
         edit 2
            set net 49.0049.1921.6818.2108.00
         next
      end
end
```

FGT4

```
config router isis
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0049.1721.0160.1004.00
         next
      end
      config redistribute "connected"
         set status enable
      end
end
```

Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

Result:

```
C    10.1.1.0/24 is directly connected, vlan1
C    10.2.2.0/24 is directly connected, vlan2
C    10.10.10.0/24 is directly connected, dmz1
```

```
R    10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

(*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

Verification on FGT2, which is the border between L1 and L2 routing levels; looking at IS-IS information

```
FGT2 # get router info isis interface
```

Result:

```
port2 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x01
Extended Local circuit ID: 0x00000003
Local SNPA: 0009.0f85.ad8c
IP interface address:
10.40.40.2/24
IPv4 interface address:

Number of active level-1 adjacencies: 0
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1221.6818.2110.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-1 Hello in 6 seconds
Next IS-IS LAN Level-2 Hello in 1 seconds
port3 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1
Local circuit ID: 0x02
Extended Local circuit ID: 0x00000004
Local SNPA: 0009.0f85.ad8d
IP interface address:
10.30.30.2/24
IPv4 interface address:
Level-1 Metric: 10/10, Priority: 64, Circuit ID: 1221.6818.2110.02
Number of active level-1 adjacencies: 1
Next IS-IS LAN Level-1 Hello in 2 seconds

FGT2 # get router info isis neighbor
```

Result:

System Id	Interface	SNPA	State	Holdtime	Type	Protocol
1921.6818.2108	port2	0009.0f04.0794	Up	22	L2	IS-IS
1921.6818.2136	port3	0009.0f85.acf7	Up	29	L1	IS-IS

Verification on FGT3, which is border between 2 areas; looking at IS-IS information

IS-IS router CLI commands available:

```
FGT3 # get router info isis ?
```

Result:

```
interface                       show isis interfaces
neighbour                       show CLNS neighbor adjacencies
is-neighbour                    show IS neighbor adjacencies
database                        show IS-IS link state database
route                           show IS-IS IP routing table
topology                        show IS-IS paths
```

Example of interface status and neighbors:

```
FGT3 # get router info isis interface
```

Result:

```
wan1 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x01
Extended Local circuit ID: 0x00000003
Local SNPA: 0009.0f04.0794
IP interface address:
10.40.40.1/24
IPv4 interface address:
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1221.6818.2110.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-2 Hello in 3 seconds

dmz1 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x02
Extended Local circuit ID: 0x00000005
Local SNPA: 0009.0f04.0792
IP interface address:
10.50.50.1/24
IPv4 interface address:
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1721.0160.1004.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-2 Hello in 7 seconds
```

```
FGT3 # get router info isis neighbor
```

Result:

System Id	Interface	SNPA	State	Holdtime	Type	Protocol
1221.6818.2110	wan1	0009.0f85.ad8c	Up	8	L2	IS-IS
1721.0160.1004	dmz1	0009.0f52.7704	Up	8	L2	IS-IS

Verification on FGT4 that the remote subnets from RTR1 and RTR2 are in the routing table and learned with IS-IS

```
FGT4 # get router info routing-table all
```

Result:

Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP

O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

i L2 10.1.1.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.2.2.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.3.3.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.4.4.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46

i L2 10.10.10.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.11.11.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.20.20.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.30.30.0/24 [115/30] via 10.50.50.1, wan1, 00:13:55
i L2 10.40.40.0/24 [115/20] via 10.50.50.1, wan1, 00:15:30

C 10.50.50.0/24 is directly connected, wan1
C 10.60.60.1/32 is directly connected, loopback

Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

…to stop the debug type output:

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

Chapter 4 - Authentication

Change log

Date	Change Description
2017-04-06	Added information regarding fall-through authentication policies.
2016-09-07	Added information regarding user disclaimer page for ethernet interface captive portals.
2016-04-25	Improved diagrams.
2016-04-13	Added RADIUS attribute support, Framed-IP-Address, for SSL VPN authentication.
2016-03-09	Added information re: LDAP user group support in PAP/CHAP protocols. Minor other updates.
2015-12-18	Improved Examples and Troubleshooting on page 599
2015-12-17	Improved Monitoring authenticated users on page 596
2015-12-14	Improved SSO using RADIUS accounting records on page 589
2015-11-09	Improved Agent-based FSSO on page 545
2015-10-29	Improved Single Sign-On to Windows AD on page 537
2015-10-22	Improved Single Sign-On using a FortiAuthenticator unit on page 533
2015-10-14	Improved Certificate-based authentication on page 514
2015-10-09	Improved Captive portals on page 506
2015-10-02	Improved Configuring authenticated access on page 489
2015-09-25	Improved Managing Guest Access on page 483
2015-06-20	Improved Users and user groups on page 463
2015-05-22	Improved Authentication servers on page 440
2015-04-14	Updated Introduction to authentication on page 431
2015-03-31	Initial release.

This Handbook chapter contains the following sections:

Introduction to authentication describes some basic elements and concepts of authentication.

Authentication servers describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

Users and user groups describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

Managing Guest Access explains how to manage temporary accounts for visitors to your premises.

Configuring authenticated access provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

Captive portals describes how to authenticate users through a web page that the FortiGate unit presents in response to any HTTP request until valid credentials are entered. This can be used for wired or WiFi network interfaces.

Certificate-based authentication describes authentication by means of X.509 certificates.

Single Sign-On using a FortiAuthenticator unit describes how to use a FortiAuthenticator unit as an SSO agent that can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit. Users can also log on through a FortiAuthenticator-based web portal or the FortiClient SSO Mobility Agent.

Single Sign-On to Windows AD describes how to set up Single Sign-On in a Windows AD network by configuring the FortiGate unit to poll domain controllers for information user logons and user privileges.

Agent-based FSSO describes how to set up Single Sign-On in Windows AD, Citrix, or Novell networks by installing Fortinet Single Sign On (FSSO) agents on domain controllers. The FortiGate unit receives information about user logons and allows access to network resources based on user group memberships.

SSO using RADIUS accounting records describes how to set up Single Sign-On in a network that uses RADIUS authentication. In this configuration, the RADIUS server send RADIUS accounting records to the FortiGate unit when users log on or off the network. The record includes a user group name that can be used in FortiGate security policies to determine which resources each user can access.

Monitoring authenticated users describes FortiOS authenticated user monitor screens.

Examples and Troubleshooting provides configuration examples and troubleshooting suggestions.

Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

- What is authentication?
- Methods of authentication
- Types of authentication
- User's view of authentication
- FortiGate administrator's view of authentication

What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

- Local password authentication
- Server-based password authentication
- Certificate-based authentication
- Two-factor authentication

Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You can create local user accounts in the web-based manager under **User & Device > User > User Definition**. This page is also used to create accounts where an external authentication server stores and verifies the password.

Server-based password authentication

Using external authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server. FortiOS supports the use of LDAP, RADIUS, TACACS+, AD or POP3 servers for authentication.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit, but instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a Certificate Authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the Certificate Authority (CA) that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a Certificate Revocation List (CRL). Certificate status can also be checked online using Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key and vice versa. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

Certificate authorities

A certificate authority can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see RSA ACE (SecurID) servers on page 458.

Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see Certificate on page 468.

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one time passcode (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see Two-factor authentication on page 467

Types of authentication

FortiOS supports two different types of authentication based on your situation and needs.

Security policy authentication is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users as needed, and it supports a number of authentication protocols to easily fit with your existing network.

Virtual Private Network (VPN) authentication enables secure communication with hosts located outside the company network, making them part of the company network while the VPN tunnel is operating. Authentication applies to the devices at both ends of the VPN and optionally VPN users can be authenticated as well.

Security policy authentication

Security policies enable traffic to flow between networks. Optionally, the policy can allow access only to specific originating addresses, device types, users or user groups. Where access is controlled by user or user group, users must authenticate by entering valid username and password credentials.

The user's authentication expires if the connection is idle for too long, 5 minutes by default but that can be customized.

Security policies are the mechanism for FSSO, NTLM, certificate based, and RADIUS SSO authentication.

FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See Introduction to agent-based FSSO on page 545.

NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user's credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see NTLM authentication on page 499 and FSSO NTLM authentication support on page 551.

Certificates

Certificates can be used as part of a policy. All users being authenticated against the policy are required to have the proper certificate. See Certificate-based authentication on page 514

RADIUS SSO

RADIUS Single Sign-On (RSSO) is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information.

That information identifies the user and user group, which is then matched using a security policy. See SSO using RADIUS accounting records on page 589.

FortiGuard Web Filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- Authenticating IPsec VPN peers (devices)
- Authenticating IPsec VPN users
- Authenticating SSL VPN users
- Authenticating PPTP and L2TP VPN users

Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a preshared key, RSA X.509 certificate, or a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a preshared key, also called a shared secret. The preshared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The preshared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of preshared key authentication is that it can be difficult to securely distribute and update the preshared keys.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see Certificate-based authentication on page 514.

You can supplement either preshared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the **Remote Gateway** to **Dialup User**.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common preshared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique preshared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the FortiGate CLI Reference.

Single Sign-On authentication for users

“Single Sign-On” means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. FortiGate units directly provide Single Sign On capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

In combination with a FortiAuthenticator unit, the FortiGate unit can provide Single Sign-On capability that integrates multiple external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP. The FortiAuthenticator unit gathers user logon information from all of these sources and sends it to the FortiGate unit.

Through the SSO feature, the FortiGate unit knows the username, IP address, and external user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about SSO, see

- Single Sign-On using a FortiAuthenticator unit on page 533
- Agent-based FSSO on page 545

User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects **Continue** or **Login**. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is

required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.
4. Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
5. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see Troubleshooting on page 614.

General authentication settings

Go to **User & Device > Authentication > Settings** to configure authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet

The selections made in the **Protocol Support** list of **Authentication Settings** control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default Fortinet certificate.

Authentication Timeout	Enter a length of time in minutes, from 1 to 1440 (24 hours). Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 5.
Protocol Support	Select the protocols to challenge during firewall user authentication.
Certificate	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
Apply	Select to apply the selections for user authentication settings.

Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

Mac OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

This section includes the following topics:

- FortiAuthenticator servers
- RADIUS servers
- LDAP servers
- TACACS+ servers
- POP3 servers
- SSO servers
- RSA ACE (SecurID) servers

FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the FortiAuthenticator Administration Guide.

RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See Membership in multiple groups on page 480.

RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPsec tunnels by placing the RADIUS server behind another VPN gateway.

RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type
1	Acct-Session-ID	Unique number assigned to each start and stop record to make it easy to match them, and to eliminate duplicate records.	44
2	Username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See Vendor-specific attributes on page 443	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided. Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service. Used to charge the user for the amount of traffic they used.	43

The following table describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

RADIUS attributes sent in RADIUS accounting message

	RADIUS Attributes						
Authentication Method	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Web	X	X	X		X		
XAuth of IPsec (without DHCP)	X	X	X		X		
XAuth of IPsec (with DHCP)	X	X	X	X	X		
PPTP/L2TP (in PPP)	X	X	X	X	X	X	X
SSL-VPN	X	X	X	X	X		

Vendor-specific attributes

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12356.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (http://kb.forticare.com) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
Fortinet's VSA's
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name   1   string
ATTRIBUTE Fortinet-Client-IP-Address   2   ipaddr
ATTRIBUTE Fortinet-Vdom-Name   3   string
ATTRIBUTE Fortinet-Client-IPv6-Address   4   octets
ATTRIBUTE Fortinet-Interface-Name   5   string
ATTRIBUTE Fortinet-Access-Profile   6   string
#
# Integer Translations
#
END-VENDOR Fortinet
```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

Role Based Access Control

In Role Based Access Control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, a security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on security policies, see Authentication in security policies on page 492.

Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specify the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addresses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 464.

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
   set radius-port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See Example — wildcard admin accounts - CLI on page 451.

To configure the FortiGate unit for RADIUS authentication - web-based manager:

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**.

Name	A name to identify the RADIUS server on the FortiGate unit.
Primary Server Name/IP	Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.
Primary Server Secret	Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long. This must match the secret on the RADIUS primary server.
Secondary Server Name/IP	Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.

Secondary Server Secret	Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long. This must match the secret on the RADIUS secondary server.
Authentication Scheme	If you know the RADIUS server uses a specific authentication protocol, select it from the list. Otherwise select **Use Default Authentication Scheme**. The Default option will usually work.
NAS IP/ Called Station ID	Enter the IP address to be used as an attribute in RADIUS access requests. **NAS-IP-Address** is RADIUS setting or IP address of FortiGate interface used to talk to RADIUS server, if not configured. **Called Station ID** is same value as NAS-IP Address but in text format.
Include in every User Group	When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

3. Select **OK**.

To configure the FortiGate unit for RADIUS authentication - CLI example:

```
config user radius
   edit ourRADIUS
      set auth-type auto
      set server 10.11.102.100
      set secret radiusSecret
   end
```

For more information about RADIUS server options, refer to the FortiGate CLI Reference.

Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port number> <secret>
```

For the port number, enter `-1` to use the default port. Otherwise enter the port number to check.

LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

- Components and topology
- LDAP directory organization
- Configuring the FortiGate unit to use an LDAP server
- Example — wildcard admin accounts - CLI
- Example of LDAP to allow Dial-in through member-attribute - CLI
- Troubleshooting LDAP

Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating user names and passwords. FortiGate LDAP supports all LDAP servers

compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

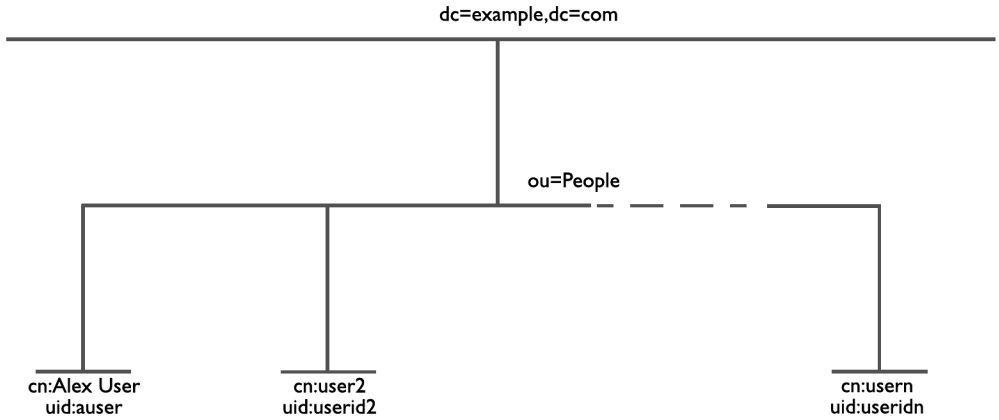
LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is ou=People,dc=example,dc=com.

LDAP object hierarchy



In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown`(cn). Also note the dn is `ou=People, dc=example, dc=com`.

Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 464.

To configure the FortiGate unit for LDAP authentication - web-based manager:

1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the LDAP server.
3. In **Server Name/IP** enter the server's FQDN or IP address.
4. If necessary, change the **Server Port** number. The default is port 389.
5. Enter the **Common Name Identifier** (20 characters maximum).
   `cn` is the default, and is used by most LDAP servers.
6. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
   The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
   If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See Using the Query icon on page 450.
7. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
   The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
   If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See Using the Query icon on page 450.
8. In **Bind Type**, select **Regular**.
9. In **User DN**, enter the LDAP administrator's distinguished name.
10. In **Password**, enter the LDAP administrator's password.
11. Select **OK**.

To verify your Distinguished Name field is correct, you can select the **Test** button. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

To configure the FortiGate unit for LDAP authentication - CLI example:

```
config user ldap
   edit ourLDAPsrv
      set server 10.11.101.160
      set cnid cn
      set dn cn=users,dc=office,dc=example,dc=com
      set type regular
      set username cn=administrator,cn=users,dc=office,dc=example,dc=com
      set password w5AiGVMLkgyPQ
      set password-expiry-warning enable
      set password-renewal enable
   end
```

password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the LDAP server when a password is expiring or has expired using server controls or error codes.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon but only to change their password.

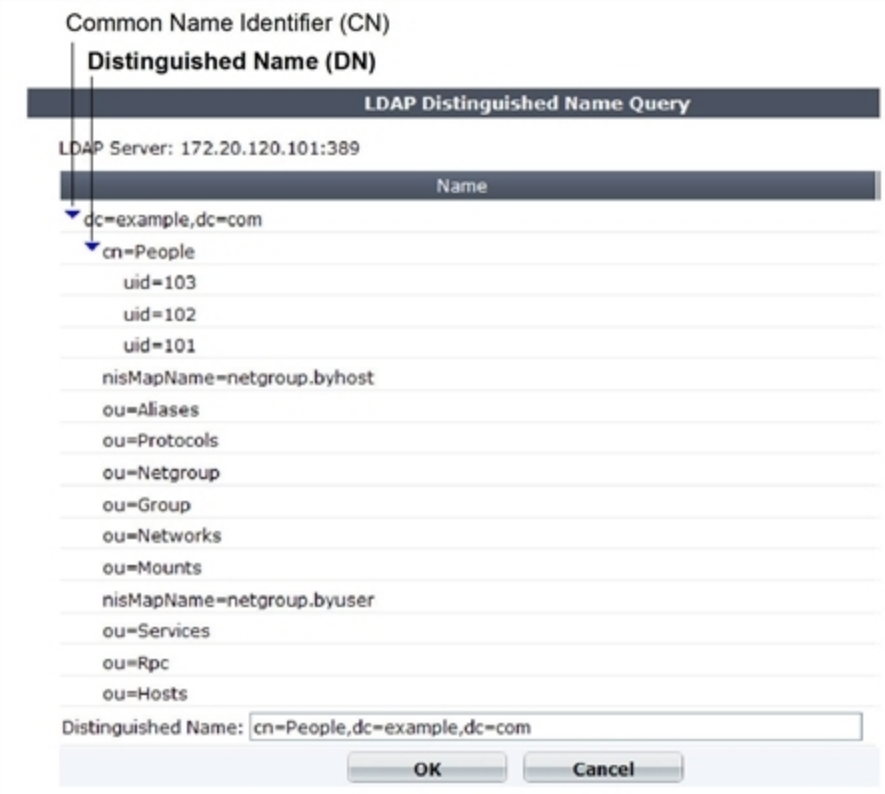
When changing passwords on a Windows AD system, the connection must be SSL-protected.

Using the Query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

LDAP server Distinguished Name Query tree



Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid system updates or changes that would otherwise require changes to the LDAP administrator account configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADIUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account

creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible. If a specific value is not mentioned, it is set to its default value.

Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

To configure LDAP server - CLI:

```
config user ldap
   edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=example,DC=com,DC=au"
      set type regular
      set username "CN=Administrator,CN=Users,DC=example,DC=COM”
      set password *
      set group-member-check group-object
      set group-object-filter (&
          (objectcategory=group)member="CN=GRP,OU=training,DC=example,DC=COM"))
   next
end
```

To configure the user group and add the LDAP server - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
         config match
            edit 1
               set server-name "ldap_server"
               set group-name "CN=GRP,OU=training,DC=example,DC=COM"
            next
         end
      next
   end
```

Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

To configure the admin account - CLI:

```
config system admin
```

```
    edit "test"
      set remote-auth enable
      set accprofile "super_admin"
      set wildcard enable
      set remote-group "ldap_grp"
    next
end
```

For troubleshooting, test that the admin account is operational, and see Troubleshooting LDAP on page 454.

Example of LDAP to allow Dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the “Allow Dial-In” property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to “TRUE”.

This same procedure can be used for other member attributes, as your system requires.

Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to “TRUE” for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
   edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=fortinet,DC=com,DC=au"
      set type regular
      set username "fortigate@example.com"
      set password ******
      set member-attr "msNPAllowDialin"
   next
end
```

Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

To configure LDAP group settings - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
      config match
```

```
        edit 1
           set server-name "ldap"
           set group-name "TRUE"
        next
     end
  end
```

Once these settings are in place, users can authenticate.

Troubleshooting LDAP

The examples in this section use the values from the previous example.

LDAP user test

A quick way to see if the LDAP configuration is correct is to run a diagnose CLI command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

`'ldap_server' is not a valid ldap server name` — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

`authenticate 'netAdmin' against 'ldap_server' failed!` — the user `netAdmin` does not exist on `ldap_server`, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the “Allow Dial-in” attribute is still set to “TRUE” and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the “Allow Dial-in” attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS's UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

Authentication protocols

Protocol	Definition
ASCII	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
PAP	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
CHAP	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.
MS-CHAP	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
default	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 464.

The TACACS+ page in the web-based manager is not available until a TACACS+ server has been configured in the CLI. For more information see the CLI Reference.

To configure the FortiGate unit for TACACS+ authentication - web-based manager:

1. Go to **User & Device > Authentication > TACACS+ Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server.
Authentication Type	Select the authentication type to use for the TACACS+ server. **Auto** tries PAP, MSCHAP, and CHAP (in that order).

To configure the FortiGate unit for TACACS+ authentication - CLI:

```
config user tacacs+
   edit tacacs1
      set authen-type auto
      set key abcdef
      set port 49
      set server 192.168.0.101
   end
```

POP3 servers

FortiOS can authenticate users who have accounts on POP3 or POP3s email servers. POP3 authentication can be configured only in the CLI.

To configure the FortiGate unit for POP3 authentication:

```
config user pop3
   edit pop3_server1
      set server pop3.fortinet.com
      set secure starttls
      set port 110
   end
```

To configure a POP3 user group:

```
config user group
   edit pop3_grp
      set member pop3_server1
   end
```

A user group can list up to six POP3 servers as members.

SSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends to the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to

maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the FortiAuthenticator Administration Guide.

Single Sign-on Agent configuration settings

The following are SSO configuration settings in **User & Device > Authentication > Single Sign-On**.

SSO Server List

Lists all the collector agents' lists that you have configured. On this page, you can create, edit or delete FSSO agents. There are different types of FSSO agents, each with its own settings.

Note: You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the Fortinet unit switches to the next one in its list of up to five collector agents.

Create New	Creates a new agent. When you select **Create New**, you are automatically redirected to the New page.
Edit	Modifies the settings for the selected SSO server. To remove multiple entries from the list, for each servers you want removed, select the check box and then select **Delete**. To remove all agents from the list, on the FSSO Agent page, select the check box at the top of the check box column and then select **Delete**.
Delete	Removes an agent from the list on the page.

Settings when Type is Poll Active Directory Server	
Server IP/Name	The IP address of the domain controller (DC).
User	The user ID used to access the domain controller.
Password	Enter the password for the account used to access the DC.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
Enable Polling	Enable to allow the FortiGate unit to poll this DC.
Users/Groups	A list of user and user group names retrieved from the DC.

Settings when Type is Fortinet Single Sign On Agent	
Name	Enter a name for the SSO server.
Primary Agent IP/Name **Secondary Agent IP/Name**	Enter the IP address or name of the Directory Service server where this SSO agent is installed. The maximum number of characters is 63.
Password	Enter the password for the collector agent. This is required only if you configured your Fortinet Single Sign On Agent collector agent to require authenticated access.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
More FSSO agents	Select to add up to three additional SSO agents.
Users/Groups	A list of user and user group names retrieved from the server.

Settings when Type is RADIUS Single Sign On Agent	
Use RADIUS Shared Secret	Enable
Shared Secret	Enter the RADIUS server shared secret.
Send RADIUS Responses	Enable.

RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

Components

When using SecurID, users carry a small device or “token” that generates and displays a pseudo-random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that

information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- to configure the RSA SecurID 130 Appliance
  or
- to configure the FortiGate unit as an Agent Host on the RSA ACE/Server
- to configure the FortiGate unit to use the RADIUS server
- to create a SecurID user group
- to configure a security policy with SecurID authentication

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP address of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

To configure the RSA SecurID 130 Appliance

1. Go to the IMS Console for SecurID and logon.
2. Go to **RADIUS > RADIUS Clients**, and select **Add New.**
3. Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
Client Name	FortiGate
Associated RSA Agent	FortiGate

RADIUS Client Settings	
IP Address	192.168.100.3 The IP address of the FortiGate unit internal interface.
Make / Model	Select Standard Radius
Shared Secret	fortinet123 The RADIUS shared secret.
Accounting	Leave unselected
Client Status	Leave unselected

To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1. On the RSA ACE/Server computer, go to **Start > Programs > RSA ACE/Server**, and then **Database Administration - Host Mode**.
2. On the **Agent Host** menu, select **Add Agent Host**.
3. Enter and save the following information.

Name	FortiGate
Network Address	192.168.100.3 The IP address of the FortiGate unit.
Secondary Nodes	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

To configure the FortiGate unit to use the RADIUS server

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	RSA
Primary Server IP/Name	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.
Primary Server Secret	fortinet123
Authentication Scheme	Select **Use Default Authentication Scheme**.

To create a SecurID user group

1. Go to **User & Device > User > User Groups**, and select **Create New**.
2. Enter the following information.

Name	RSA_group
Type	Firewall

3. In **Remote Groups**, select **Add**, then select the RSA server.
4. Select **OK**.

To create a SecurID user:

1. Go to **User & Device > User > User Definition**, and select **Create New**.
2. Use the wizard to enter the following information, and then select **Create**.

User Type	Remote RADIUS User
User Name	wloman
RADIUS Server	RSA
Contact Info	(optional) Enter Email or SMS information
User Group	RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diagnose test authserver radius RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- Security policy
- IPsec VPN XAuth
- PPTP VPN
- SSL VPN

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

Security policy

To use SecurID in a security policy, you must include the SecurID user group in a security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

To configure a security policy with SecurID authentication

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Enter:

Incoming Interface	internal
Source Address	all
Source User(s)	securIDgrp
Outgoing Interface	wan1
Destination Address	all
Schedule	always

Services	HTTP, FTP, POP3
Action	ACCEPT
NAT	On
Shared Shaper	On, if you want to either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy. Use the default shaper **guarantee-100kbps**.
Log Allowed Traffic	On, if you want to generate usage reports on traffic authenticated with this policy.

4. Select **OK**.
   The SecurID security policy is configured.

For more detail on configuring security policies, see the FortiOS Handbook FortiGate Fundamentals guide.

IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring user authentication in addition to the preshared key.

When creating an IPsec VPN using the wizard (**VPN > IPsec > Wizard**), select the SecurID **User Group** on the Authentication page. Members of the SecurID group are required to enter their SecureID code to authenticate.

For more on XAuth, see Configuring XAuth authentication on page 502

PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

SSL VPN

You need to map the SecurID user group to the portal that will serve SecurID users and include the SecurID user group in the **Source User(s)** field in the security policy.

To map the SecurID group to an SSL VPN portal:

1. Go to **VPN > SSL > Settings**.
2. In **Authentication/Portal Mapping**, select **Create New**.
3. Enter

Users/Groups	securIDgrp
Portal	Choose the portal.

4. Select **OK**.

Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see Authentication servers on page 440.

This section contains the following topics:

- Users
- User groups

Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

User type	Authentication
Local user	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
Remote user	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server. FortiOS supports LDAP, RADIUS, and TACACS+ servers.
Authentication server user	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
FSSO user	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
PKI or Peer user	A Public Key Infrastructure (PKI) or peer user is a digital certificate holder who authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.
IM Users	IM users are not authenticated. The FortiGate unit can allow or block each IM user name from accessing the IM protocols. A global policy for each IM protocol governs access to these protocols by unknown users.
Guest Users	Guest user accounts are temporary. The account expires after a selected period of time.

This section includes:

- Local and remote users
- PKI or peer users
- Two-factor authentication
- FortiToken
- Monitoring users

Local and remote users

Local and remote users are defined on the FortiGate unit in **User & Device > User > User Definition**.

Create New	Creates a new user account. When you select **Create New**, you are automatically redirected to the User Creation Wizard.
Edit User	Modifies a user's account settings. When you select **Edit**, you are automatically redirected to the Edit User page.
Delete	Removes a user from the list. Removing the user name removes the authentication configured for the user. The **Delete** icon is not available if the user belongs to a user group. To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select **Delete**. To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select **Delete**.
User Name	The user name. For a remote user, this username must be identical to the username on the authentication server.
Type	Local indicates a local user authenticated on the FortiGate unit. For remote users, the type of authentication server is shown: LDAP, RADIUS, or TACACS+.
Two-factor Authentication	Indicates whether two-factor authentication is configured for the user.
Ref.	Displays the number of times this object is referenced by other objects. Select the number to open the Object Usage window and view the list of referring objects. The list is grouped into expandable categories, such as Firewall Policy. Numbers of objects are shown in parentheses. To view more information about the referring object, use the icons: • **View the list page for these objects** – available for object categories. Goes to the page where the object is listed. For example, if the category is User Groups, opens User Groups list. • **Edit this object** – opens the object for editing. • **View the details for this object** – displays current settings for the object.

To create a local or remote user account - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. On the **Choose User Type** page select:

Local User	Select to authenticate this user using a password stored on the FortiGate unit.
Remote RADIUS User **Remote TACACS+ User** **Remote LDAP User**	To authenticate this user using a password stored on an authentication server, select the type of server and then select the server from the list. You can select only a server that has already been added to the FortiGate unit configuration.

3. Select **Next** and provide user authentication information.
   For a local user, enter the **User Name** and **Password**.
   For a remote user, enter the **User Name** and the server name.
4. Select **Next** and enter **Contact Information**.
   If email or SMS is used for two-factor authentication, provide the email address or SMS cell number at which the user will receive token password codes. If a custom SMS service is used, it must already be configured in **System > Config > Advanced >SMS Service**. See FortiToken on page 470.
5. Select **Next**, then on the **Provide Extra Info** page enter

Two-factor Authentication	Select to enable two-factor authentication. Then select the Token (FortiToken or FortiToken Mobile) for this user account. See Associating FortiTokens with accounts on page 474.
User Group	Select the user groups to which this user belongs.

6. Select **Create**.

To create a local user - CLI example:

Locally authenticated user

```
config user local
   edit user1
      set type password
      set passwd ljt_pj2gpepfdw
   end
```

To create a remote user - CLI example:

```
config user local
   edit user2
      set type ldap
      set ldap_server ourLDAPsrv
   end
```

For a RADIUS or TACACS+ user, set `type` to `radius` or `tacacs+`, respectively.

To create a user with FortiToken Mobile two-factor authentication - CLI example:

```
config user local
   edit user5
      set type password
      set passwd ljt_pj2gpepfdw
      set two_factor fortitoken
      set fortitoken 182937197
   end
```

Remote users are configured for FortiToken two-factor authentication similarly.

To create a user with SMS two-factor authentication using FortiGuard messaging Service - CLI example:

```
config user local
   edit user6
      set type password
      set passwd 3ww_pjt68dw
      set two_factor sms
      set sms-server fortiguard
      set sms-phone 1365984521
   end
```

Removing users

Best practices dictate that when a user account is no longer in use, it should be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is referenced by any configuration objects, those references must be removed before the user can be deleted. See Removing references to users on page 466.

To remove a user from the FortiOS configuration - web-based manager:

1. Go to **User & Device > User > User Definition**.
2. Select the check box of the user that you want to remove.
3. Select **Delete**.
4. Select **OK**.

To remove a user from the FortiOS configuration - CLI example:

```
config user local
   delete user4444
end
```

Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

To remove references to a user - web-based manager

1. Go to **User & Device > User > User Definition**.
2. If the number in the far right column for the selected user contains any number other than zero, select it.

3. A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see Certificates overview on page 515.

To define a peer user you need:

- a peer username
- the text from the subject field of the user's certificate, or the name of the CA certificate used to validate the user's certificate

Creating a peer user

The peer user can be configured only in the CLI.

To create a peer user for PKI authentication - CLI example:

```
config user peer
   edit peer1
      set subject peer1@mail.example.com
      set ca CA_Cert_1
   end
```

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings, see the FortiGate CLI Reference.

Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for your logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need to ensure you have a second administrator account configured to guarantee administrator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

The methods of two-factor authentication include:

- Certificate
- Email
- SMS
- FortiToken

Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

To create a peer user with two-factor authentication - CLI example

```
config user peer
   edit peer1
      set subject E=peer1@mail.example.com
      set ca CA_Cert_1
      set two-factor enable
      set passwd fdktguefheygfe
   end
```

For more information on certificates, see Certificates overview on page 515.

Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time,it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

To configure an email provider - web-based manager:

1. Go to **System > Config > Advanced > Email Service**.
2. Enter **SMTP Server** and **Default Reply To** address.
3. If applicable, enable **Authentication** and enter the **SMTP User** and **Password** to use.
4. Select a **Security Mode**, options are: **None**, **SMTPS** or **STARTTLS**.
5. Enter the **Port** number, the default is 25.
6. Select **Apply**.

To configure an email provider - CLI:

```
config system email-server
   set server <server_domain-name>
   set reply-to <Recipient_email_address>
end
```

To enable email two-factor authentication - web-based manager:

1. To modify an administrator account, go to **System > Admin > Administrators**. To modify a user account go to **User & Device > User > User Definition**.
2. Edit the user account.
3. Enable and enter the user's **Email Address**.
4. Select **Enable Two-factor Authentication**.
5. Select **Email based two-factor authentication**.
6. Select **OK**.

If **Email based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

To enable email two-factor authentication - CLI:

```
config user local
   edit <user_name>
      set email-to <user_email>
      set two-factor email
   end
```

SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

FortiGuard Messaging Service include 4 SMS Messages at no cost. If you need more, you should acquire a license through support.fortinet.com or via customer service.

If you do not use the FortiGuard Messaging Service, you need to configure an SMS service.

To configure an SMS service for your FortiGate unit - web-based manager:

1. Go to **System > Config > Advanced**.
2. In **SMS Service**, select **Create New**.
3. Enter a **Name** for the SMS service and the service **Address** (domain name), then select **OK**.
4. Select **Apply**.

To configure an SMS service - CLI:

```
config system sms-server
   edit <provider_name>
      set mail-server <server_domain-name>
   next
end
```

To configure SMS two-factor authentication - web-based manager:

1. To modify an:
   - administrator account, go to **System > Admin > Administrators, or**
   - user account go to **User & Device > User > User Definition**.
2. Edit the user account.
3. Select SMS and either:
   - Select **FortiGuard Messaging Service**
     or
   - Select **Custom** and then choose the **SMS Provider** to use.
4. Select the **Country/Region**.
5. Enter the phone number of the mobile device that will receive the SMS text messages.
6. Select **Enable Two-factor Authentication**.
7. Select **SMS based two-factor authentication**.
8. Select **OK**.

If **SMS based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

To enable SMS two-factor authentication - CLI:

```
config user local
   edit <user_name>
      set sms-phone <user_phone>
      set sms-server fortiguard
      set two-factor sms
   end
```

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

There is also a mobile phone application, FortiToken Mobile, that performs much the same function.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPsec VPN, SSL VPN, and even Administrators. See Associating FortiTokens with accounts on page 474.

A FortiToken can be associated with only one account on one FortiGate unit.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See FortiToken maintenance on page 475.

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

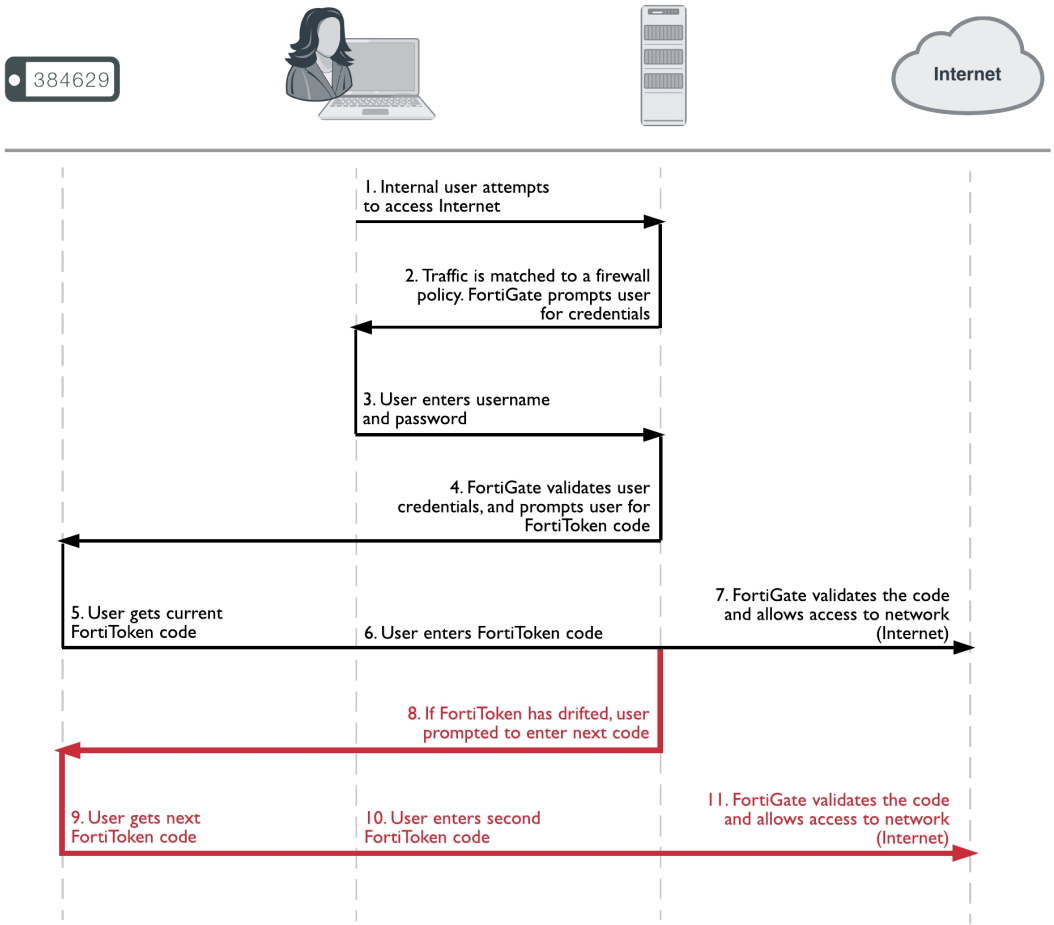
1. Adding FortiTokens to the FortiGate
2. Activating a FortiToken on the FortiGate
3. Associating FortiTokens with accounts

The FortiToken authentication process

The steps during FortiToken two-factor authentication are as follows.

1. User attempts to access a network resource.
2. FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.
3. User enters their username and password.
4. FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.
5. User gets the current code from their FortiToken device.
6. User enters current code at the prompt.
7. FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.
   The following steps are needed only if the time on the FortiToken has drifted and needs to be re-synchronized with the time on the FortiGate unit.
8. If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.
9. User gets the next code from their FortiToken device
10. User enters the second code at the prompt.
11. FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step "Users and user groups" on page 463.

The FortiToken authentication process is illustrated below:



When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time. The serial number file must be a text file with one FortiToken serial number per line.

One FortiToken can be added to multiple FortiGate units. This is useful for maintaining two-factor authentication for employees over multiple office locations, such as for employees who travel frequently between offices.

To manually add a FortiToken to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token** or **Mobile Token**.
4. Enter one or more FortiToken serial numbers (hard token) or activation codes (mobile token).
5. Select **OK**.

For mobile token, you receive the activation code in the license certificate once you purchase a license. FortiOS include a license for two mobile token at no cost.

To import multiple FortiTokens to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token**.
4. Select **Import**.
5. Select **Serial Number File** or **Seed File**, depending on which file you have.
6. Browse to the local file location on your local computer.
7. Select **OK**.
   The file is imported.
8. Select **OK**.

To add two FortiTokens to the FortiGate - CLI:

```
config user fortitoken
   edit <serial_number>
   next
   edit <serial_number2>
   next
end
```

Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts.The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

To activate a FortiToken on the FortiGate unit - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select one or more FortiTokens with a status of Available.

3. Right-click the FortiToken entry and select **Activate**.
4. Select **Refresh**.
   The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

To activate a FortiToken on the FortiGate unit - CLI:

```
config user fortitoken
   edit <token_serial_num>
      set status activate
   next
end
```

Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

To add a FortiToken to a local user account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **User & Device > User > User Definition**, and edit the user account.
3. Select **Email Address** and enter user's email address.
4. Select **Enable Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code**to be sent to the email address configured previously. The user will use this code to activate his mobile token. An **Email Service** has to be set under **System > Config > Advanced**in order to send the activation code.

To add a FortiToken to a local user account - CLI:

```
config user local
   edit <username>
      set type password
      set passwd "myPassword"
      set two-factor fortitoken
      set fortitoken <serial_number>
      set email-to "username@example.com"
      set status enable
   next
   end
```

To add a FortiToken to an administrator account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **System > Admin > Administrators**, and edit the admin account.
   This account is assumed to be configured except for two-factor authentication.
3. Select **Email Address** and enter admin's email address.
4. Select **Enable Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code**to be sent to the email address configured previously. The admin will use this code to activate his mobile token. An **Email Service** has to be set under **System > Config > Advanced**in order to send the activation code.

To add a FortiToken to an administrator account - CLI:

```
config system admin
   edit <username>
      set password "myPassword"
      set two-factor fortitoken
      set fortitoken <serial_number>
      set email-to "username@example.com"
   next
   end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` option.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

To change the status of a FortiToken between Activated and Locked - CLI:

```
config user fortitoken
   edit <token_serial_num>
      set status lock
   next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

To list the drift on all FortiTokens configured on this FortiGate unit - CLI:

```
# diag fortitoken info
```

```
FORTITOKEN DRIFT STATUS
FTK2000BHV1KRZCC 0 token already activated, and seed won't be returned
FTK2001C5YCRRVEE 0 token already activated, and seed won't be returned
FTKMOB4B94972FBA 0 provisioned
FTKMOB4BA4BE9B84 0 new
Total activated token: 0
Total global activated token: 0
Token server status: reachable
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

Monitoring users

To monitor user activity in the web-based manager, go to **User & Device > Monitor > Firewall**. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to **User & Device > Monitor > Banned User**. Displayed information about users who have been banned includes what application the triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select settings bottom at the top right of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a check box to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an * (asterisk).

For example, to create a filter to display only users with an IP address of `10.11.101.x` who authenticated using one of security policies five through eight, and who belong to the user group `Accounting`.

1. Go to **User & Device > Monitor > Firewall**.
2. Select the filter icon beside **IP address**.
3. Enter `10.11.101.` and select **Apply**.
4. Select the filter icon beside **Policy ID.**
5. Enter `5-8` and select **Apply**.
6. Select the filter icon beside **User Group.**
7. Enter `Accounting` and select **Apply**.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (username/password stored on the FortiGate unit
- a remote user account (password stored on a RADIUS, LDAP, or TACACS+ server)
- a PKI user account with digital client authentication certificate stored on the FortiGate unit
- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Security policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources. Users must be in a group and that group must be part of the security policy.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

There are four types of FortiGate user groups: Firewall, Fortinet Single Sign-On (FSSO), Guest, and RADIUS Single Sign-On (RSSO) user groups.

Firewall user groups

Firewall user groups are used locally as part of authentication. When a security policy allows access only to specified user groups, users must authenticate. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

- SSL VPN access
- IPsec VPN access
- Configuring a firewall user group
- Multiple group enforcement support
- User group timeouts

SSL VPN access

SSL VPN settings include a list of the firewall user groups that can access the SSL VPN and the SSL VPN portal that each group will use. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires a security policy where the destination is the SSL interface. For more information, see the FortiOS Handbook SSL VPN guide.

IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the **Accept peer ID in dialup group** peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

For more information, see the FortiOS Handbook IPsec VPN guide.

Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

To create a Firewall user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a name for the user group.
3. In **Type**, select **Firewall**.
4. Add user names to to the **Members** list.
5. Add authentication servers to the **Remote groups** list.
   By default all user accounts on the authentication server are members of this FortiGate user group. To include only specific user groups from the authentication server, deselect **Any** and enter the group name in the appropriate format for the type of server. For example, an LDAP server requires LDAP format, such as: cn=users,dn=office,dn=example,dn=com
   Remote servers must already be configured in **User & Device > Authentication**.
6. Select **OK**.

To create a firewall user group - CLI example:

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on `myRADIUS` external RADIUS server.

```
config user group
   edit accounting_group
      set group-type firewall
      set member User1 myRADIUS
      config match
         edit 0
            set server-name myRADIUS
            set group-name rad_accounting_group
         end
```

```
end
```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as “engineering” or “cn=users,dc=test,dc=com”.

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```
config user tacacs+
   edit myTACS
   set authorization enable
   next
end
```

For more information about user group CLI commands, see the Fortinet CLI Guide.

Multiple group enforcement support

Previously, when a user belonged to multiple user groups, this user could only access the group services that were within one group. With multiple group enforcement, a user can access the services within the groups that the user is part of.

For example, `userA` belongs to `user_group1`, `user_group2`, `user_group3`, and `user_group4`; previously `userA` could only access services within one of those four groups, typically the group that matches the first security policy. This can be annoying if HTTP access is in `user_group1`, FTP access is in `user_group2`, and email access is in `user_group3`. Now `userA` can access services within `user_group1`, `user_group2`, `user_group3`, and `user_group4`.

This feature is available only in the CLI and is enabled by default. It applies to RADIUS, LDAP, and TACACS+ servers. The new command for this feature is `auth-multi-group` found in `config user settings` and checks all groups a user belongs to for authentication.

User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings authtimeout is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 1440 minutes (24 hours).

```
config user setting
   set auth-timeout-type idle-timeout
   set auth-timeout 300
end
```

Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

To configure user group authentication idle timeout - CLI:

```
config user settings
   set auth-timeout-type idle-timeout
end
config user group
   edit example_group
      set authtimeout 5 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

To configure user group authentication hard timeout - CLI:

```
config user settings
   set auth-timeout-type hard-timeout
end
config user group
   edit example_group
      set authtimeout 1440 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place.

To configure a user group authentication new session hard timeout - CLI:

```
config user setting
   set auth-timeout-type new-session
end

config user group
   edit example_group
      set authtimeout 30 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

SSO user groups

SSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see Creating Fortinet Single Sign-On (FSSO) user groups on page 582. For complete information about installing and configuring FSSO, see Agent-based FSSO on page 545.

Configuring Peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group.

To create a peer group - CLI example:

```
config user peergrp
   edit vpn_peergrp1
      set member pki_user1 pki_user2 pki_user3
   end
```

Viewing, editing and deleting user groups

To view the list of FortiGate user groups, go to **User & Device > User > User Groups**.

Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, a Fortinet Single Sign-On Service group (FSSO), a Radius based Single Sign-On Service group (RSSO), or a guest group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

To edit a user group - web-based manager:

1. Go to **User & Device > User > User Groups**.
2. Select the user group that you want to edit.
3. Select the **Edit** button.
4. Modify the user group as needed.
5. Select **OK**.

To edit a user group - CLI example:

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
   edit Group1
   set group-type firewall
      set member user2 user4 user3
   end
```

Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to, it such as security policies. If there are, you must remove those references before you are able to delete the user group.

To remove a user group - web-based manager:

1. Go to **User & Device > User > User Groups**.
2. Select the user group that you want to remove.
3. Select the **Delete** button.
4. Select **OK**.

To remove a user group - CLI example:

```
config user group
   delete Group2
end
```

Managing Guest Access

Visitors to your premises might need user accounts on your network for the duration of their stay. If you are hosting a large event such as a conference, you might need to create many such temporary accounts. The FortiOS Guest Management feature is designed for this purpose.

A guest user account User ID can be the user's email address, a randomly generated string, or an ID that the administrator assigns. Similarly, the password can be administrator-assigned or randomly generated.

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

User's view of guest access

1. The user receives an email, SMS message, or printout from a FortiOS administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

Administrator's view of guest access

1. Create one or more guest user groups.
   All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.
2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

Configuring guest user access

To set up guest user access, you need to create at least one guest user group and add guest user accounts. Optionally, you can create a guest management administrator whose only function is the creation of guest accounts in specific guest user groups. Otherwise, any administrator can do guest management.

Creating guest management administrators

To create a guest management administrator

1. Go to **System > Admin > Administrators** and create a regular administrator account.
   For detailed information see the System Administration chapter.
2. Select **Restrict to Provision Guest Accounts**.
3. In **Guest Groups**, add the guest groups that this administrator manages.

Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

To create a guest user group:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information:

Name	Enter a name for the group.
Type	Guest
Enable Batch Account Creation	Create multiple accounts automatically. When this is enabled: • **User ID** and **Password** are set to **Auto-Generate**. • The user accounts have only **User ID, Password**, and **Expiration** fields. Only the **Expiration** field is editable. If the expiry time is a duration, such as "8 hours", this is the time after first login. • You can print the account information. Users do not receive email or SMS notification. See To create multiple guest user accounts automatically on page 485.
User ID	Select one of: • Email — User's email address • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random user ID
Password	Select one of: • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random password • Disable — no password
Expire Type	Choose one of: • Immediately — expiry time is counted from creation of account • After first login — expiry time is counted from user's first login
Default Expire Time	Set the expire time. The administrator can change this for individual users.
Enable Name	If enabled, user must provide a name.
Enable Sponsor	If enabled, user form has Sponsor field. Select **Required** if required.
Enable Company	If enabled, user form has Company field. Select **Required**if required.
Enable Email	If enabled, user is notified by email.
Enable SMS	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used. You can add SMS providers in **System > Config > Messaging Servers**.

Creating guest user accounts

Guest user accounts are not the same as local user accounts created in **User & Device > User > User Definition**. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in **User & Device > User > Guest Management**.

To create a guest user account

1. Go to **User & Device > User > Guest Management.**
2. In **Guest Groups**, select the guest group to manage.

3. Select **Create New** and fill in the fields in the **New User** form.
   Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.
4. Select **OK**.

To create multiple guest user accounts automatically

1. Go to **User & Device > User > Guest Management.**
2. In **Guest Groups**, select the guest group to manage.
   The guest group must have the **Enable Batch Guest Account Creation** option enabled.
3. Select **Create New > Multiple Users**.
   Use the down-pointing caret to the right of **Create New**.
4. Enter **Number of Accounts**.
5. Optionally, change the **Expiration**.
6. Select **OK**.

Guest Management Account List

Go to **User & Device > User > Guest Management** to create, view, edit or delete guest user accounts.

Create New	Creates a new guest user account.
Edit	Edit the selected guest user account.
Delete	Delete the selected guest user account.
Purge	Remove all expired accounts from the list.
Send	Send the user account information to a printer or to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
Refresh	Update the list.
Guest Groups	Select the guest group to list. New accounts are added to this group.
User ID	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
Expires	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

Guest access in a retail environment

Some retail businesses such as coffee shops provide free Wi-Fi Internet access for their customers. For this type of application, the FortiOS guest management feature is not required; the Wi-Fi access point is open and customers do not need logon credentials. However, the business might want to contact its customers later with promotional offers to encourage further patronage. Using an Email Collection portal, it is possible to collect customer email addresses for this purpose. The security policy grants network access only to users who provide a valid email address.

The first time a customer's device attempts to use the Wi-Fi connection, FortiOS requests an email address, which it validates. The customer's subsequent connections go directly to the Internet without interruption.

Creating an email harvesting portal

The customer's first contact with your network will be with a captive portal which presents a web page requesting an email address. When FortiOS has validated the email address, the customer's device MAC address is added to the Collected Emails device group.

To create the email collection portal:

1. Go to **WiFi & Switch Controller > WiFi Network > SSID** and edit your SSID.
2. Set **Security Mode** to **Captive Portal**.
3. Set **Portal Type** to **Email Collection**.
4. Optionally, in **Customize Portal Messages** select **Email Collection.**

You can change the portal content and appearance. See Customizing captive portal pages on page 508.

To create the email collection portal - CLI:

In this example the `freewifi` Wi-Fi interface is modified to present an email collection captive portal.

```
config wireless-controller vap
   edit freewifi
      set security captive-portal
      set portal-type email-collect
end
```

Creating the security policy

You need configure a security policy that allows traffic to flow from the Wi-Fi SSID to the Internet interface but only for members of the Collected Emails device group. This policy must be listed first. Unknown devices are not members of the Collected Emails device group, so they do not match the policy.

To create the security policy:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	freewifi
Source Address	all
Source Device Type	Collected Emails
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL

Action	ACCEPT
NAT	On

3. Select **OK**.

To create the authentication rule - CLI:

```
config firewall policy
   edit 3
      set srcintf "freewifi"
      set dstintf "wan1"
      set srcaddr "all"
      set action accept
      set devices collected-emails
      set nat enable
      set schedule "always"
      set service "ALL"
   end
```

Checking for harvested emails

In the web-based manager, go to **User & device > Device > Device Definitions**. In the CLI you can use the `diagnose user device list` command. For example,

```
FGT-100D # diagnose user device list
hosts
   vd 0 d8:d1:cb:ab:61:0f gen 35 req 30 redir 1 last 43634s 7-11_2-int
      ip 10.0.2.101 ip6 fe80::dad1:cbff:feab:610f
      type 2 'iPhone' src http c 1 gen 29
      os 'iPhone' version 'iOS 6.0.1' src http id 358 c 1
      email 'yo@yourdomain.com'
   vd 0 74:e1:b6:dd:69:f9 gen 36 req 20 redir 0 last 39369s 7-11_2-int
      ip 10.0.2.100 ip6 fe80::76e1:b6ff:fedd:69f9
      type 1 'iPad' src http c 1 gen 5
      os 'iPad' version 'iOS 6.0' src http id 293 c 1
      host 'Joes's-iPad' src dhcp
      email 'you@fortinet.com'
```

Fall-through authentication policies

User authentication policies have an implicit fall-through feature that intentionally causes policy matching to fall through to a policy lower on the list that can also match the traffic. In other words the first user policy that is matched in the policy list, based on standard policy criteria, isn't the only policy that can be matched.

Fall-through is intended to match users in different user groups with different policies. For example, consider an organization with two user groups where one group requires a web filtering profile, while the other requires virus scanning. In this example, you would edit two basic Internet access policies: policy 1 assigning **User Group A** with a **Web Filtering** profile, and policy 2 assigning **User Group B** with an **AntiVirus** profile. Both policies are also assigned to the same internal subnet, named **subnet1**.

In this configuration, all users from **subnet1** will see an authentication prompt. If the user is found in **User Group A**, the traffic is accepted by policy 1 and is filtered by the **Web Filtering** profile. If the user is found in **User Group B**, the traffic is accepted by policy 2 and is virus scanned.

The fall-through feature is required for users to be matched with policy 2. Without the fall-through feature, traffic would never be matched with policy 2.

Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

- Authentication timeout
- Password policy
- Authentication protocols
- Authentication in Captive Portals
- Authentication in security policies
- VPN authentication

Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 1440 minutes (24 hours).

To set the security authentication timeout - web-based manager:

1. Go to **User & Device > Authentication > Settings**.
2. Enter the **Authentication Timeout** value in minutes.
   The default authentication timeout is 5 minutes.
3. Select **Apply**.

SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (**Idle Timeout**) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 259 200 seconds. The default timeout is 300 seconds.

To set the SSL VPN authentication timeout - web-based manager:

1. Go to **VPN > SSL > Settings**.
2. Under **Idle Logout**, make sure that **Logout users when inactive for specified period** is enabled and enter the **Inactive For** value (seconds).
3. Select **Apply**.

Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN preshared keys.

To set a password policy in the web-based manager, go to **System > Admin > Settings**. In the CLI, use the `config system password-policy` command.

The default minimum password length on the FortiGate unit is eight characters, but up to 128 characters is permitted.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

Configuring password minimum requirement policy

Best practices dictate that passwords include:

- one or more uppercase characters
- one or more lower case characters
- one or more of the numerals
- one or more special characters.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower care, two digits, and one special character. Leave the minimum length at the default of eight characters.

To change administrator password minimum requirements - web-based manager:

1. Go to **System > Admin > Settings**.
2. Select **Enable Password Policy**.
3. Select **Must Contain at Least**.
4. Enter the following information:

Upper Case Letters	2
Lower Case Letters	4
Numbers	2
Special Characters	1

5. Under **Apply Password Policy to**, select **Administrator Password**.
6. Select **Apply**.

To change administrator password minimum requirements - CLI:

```
config system password-policy
   set status enable
```

```
    set apply-to admin-password
    set min-upper-case-letter 2
    set min-lower-case-letter 4
    set min-number 2
    set min-non-alphanumeric 1
    set change-4-characters enable
end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dictate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

Maximum logon attempts and blackout period

When you logon and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to logon before a blackout period where you cannot logon.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
   set auth-invalid-max 5
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed logon attempts has been reached, use the following CLI command:

```
config user setting
   set auth-blackout-time 300
end
```

Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see Authentication replacement messages on page 493.

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see Certificate-based authentication on page 514.

To set the authentication protocols

1. Go to **User & Device > Authentication > Settings**.
2. In **Protocol Support**, select the required authentication protocols.
3. If using HTTPS protocol support, in **Certificate**, select a Local certificate from the drop-down list.
4. Select **Apply**.

Authentication in Captive Portals

Network interfaces, including WiFi interfaces, can perform authentication at the interface level using a captive portal — an HTML form that requests the user's name and password. A captive portal is useful where all users connecting to the network interface must authenticate. Optionally, on a WiFi interface, the captive portal can be combined with a terms of service disclaimer to which the user must agree before gaining access. For more information, see Captive portals on page 506.

Once successfully authenticated, the user's session passes to the firewall.

Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. The firewall tries to match the session's user or group identity, device type, destination, etcetera to a security policy. When a match is found, the user connects to the requested destination. If no security policy matches, the user is denied access.

A user who has not already been authenticated by a captive portal, FSSO, or RSSO can match only policies where no user or user group is specified. If no such policy exists, the firewall requests authentication. If the user can authenticate and the session can be matched to a policy, the user connects to the requested destination, otherwise, the user is denied access.

This section includes:

- Enabling authentication protocols
- Authentication replacement messages
- Access to the Internet
- Configuring authentication security policies
- Identity-based policy
- NTLM authentication
- Certificate authentication
- Restricting number of concurrent user logons

Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

To enable support for authentication protocols - web-based manager:

1. Go to **User & Device > Authentication > Settings**.
2. Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.
3. Select the **Certificate** to use, for example `Fortinet_Factory`.
4. Select **Apply**.

To enable support for authentication protocols - CLI:

```
config user setting
   set auth-type ftp http https telnet
   set auth-cert Fortinet_Factory
end
```

Authentication replacement messages

A replacement message is the body of a webpage containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the FortiOS CLI Reference.

List of authentication replacement messages

Replacement message name (CLI name)	Description
Login challenge page (auth-challenge-page)	This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, “Please enter new PIN”). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified. The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN. This page uses the %%QUESTION%% tag.
Disclaimer page (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	This page prompts user to accept the displayed disclaimer when leaving the captive portal to access Internet resources. It is displayed when the captive portal type is **Authentication and Disclaimer** or **Disclaimer Only**. In the CLI, the auth-disclaimer-page-2 and auth-disclaimer-page-3 pages seamlessly extend the size of the disclaimer page from 8 192 characters to 16 384 and 24 576 characters respectively. In the web-based manager this is handled automatically. See Disclaimer on page 498.
Email token page (auth-email-token-page)	The page prompting a user to enter their email token. See Email on page 1.
FortiToken page (auth-fortitoken-page)	The page prompting a user to enter their FortiToken code. See FortiToken on page 470.

Keepalive page (auth-keepalive-page)	The HTML page displayed with security authentication keepalive is enabled using the following CLI command:
	
	`config system globalset auth-keepalive enable`
	`end`
	
	Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to **User & Device > Authentication > Settings** to set the **Authentication Timeout**.
	
	This page includes %%TIMEOUT%%.

Replacement message name (CLI name)	Description
Login failed page (auth-login-failed-page)	The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.
Login page (auth-login-page)	The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS. Prompts the user for their username and password to login. This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.
Declined disclaimer page (auth-reject-page)	The page displayed if a user declines the disclaimer page. See Disclaimer on page 498.
SMS Token page (auth-sms-token-page)	The page prompting a user to enter their SMS token. See SMS on page 469.
Success message (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to **all**. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ALL.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must **precede** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

Configuring authentication security policies

To include authentication in a security policy, the policy must specify user groups. A security policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are RADIUS SSO and FSSO Agents. See SSO using RADIUS accounting records on page 589, and Introduction to FSSO agents on page 546.

Before creating a security policy, you need to configure one or more users or user groups. For more information, see Users and user groups on page 463.

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or a security policy that specifies an FSSO user group	Agent-based FSSO on page 545.
	NTLM	See NTLM authentication on page 499.
	Certificates	See Configuring certificate-based authentication on page 526.
	RADIUS SSO	See SSO using RADIUS accounting records on page 589.
DENY	none	none

Disclaimer

A WiFi or SSL captive portal can include a disclaimer message presented after the user authenticates. The user must agree to the terms of the disclaimer to access network resources.

Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Changing the disclaimer in **System > Config > Replacement messages** is not the same as selecting to customize a disclaimer used in a captive portal. The **System > Config** location is the default message that all disclaimers inherit. The captive portal location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this portal.

To customize the disclaimer for a captive portal - web-based manager:

1. Go to **System > Network > Interface**. Either select an existing interface or create a new one.
2. Under **Security Mode**, select **Captive Portal**, and enable **Customize Portal Messages**.
3. Select the **Edit** icon. You can select and edit any of the pages. Change your text or layout as needed.

Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to **Log&Report > Log Config > Log Settings** and enable **Event Logging**. Select the events you want to log, such as **User activity event**.

When enabled, security logging will log security profile and security policy traffic.

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as security profiles features. Event logs are enabled within the Event Log page.

For more information on logging, see the FortiOS Log and Reporting guide.

For more information on specific types of log messages, see the FortiOS Log Message Reference.

You need to set the logging severity level to **Notification** when configuring a logging location to record traffic log messages.

To enable logging within an existing security policy - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4**.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select **Edit**.
4. To log all general firewall traffic, select the check box beside **Log Allowed Traffic**, and choose to enable **Security Events** or **All Sessions**.
5. Select **OK**.

Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

Identity-based policies also support Single Sign-On operation. The user groups selected in the policy are of the Fortinet Single Sign-On (FSSO) type.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see Certificate authentication on page 500.

With identity-based policies, the FortiGate unit allows traffic that matches the source and destination addresses, device types, and so on. This means specific security policies must be placed **before** more general ones to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See Disclaimer on page 498.

Types of authentication also available in identity-based policies are

- NTLM authentication
- Certificate authentication

NTLM authentication

NT LAN Manager (NTLM) protocol can be used as a fallback for authentication when the Active Directory (AD) domain controller is unreachable. NTLM uses the web browser to send and receive authentication information. See "NTLM" and "FSSO NTLM authentication support".

To enable NTLM

1. Edit the policy in the CLI to enable NTLM. For example, if the policy ID is 4:
2. Go to **Policy & Objects > Policy > IPv4** and note the **ID** number of your FSSO policy.
3. The policy must have an FSSO user group as **Source User(s)**. There must be at least one FSSO Collector agent configured on the FortiGate unit.

```
config firewall policy
   edit 4
      set ntlm enable
   end
```

NTLM guest access

Guest profile access may be granted to users who fail NTLM authentication, such as visitors who have no user credentials on the network. To allow guest user access, edit the FSSO security policy in the CLI, like this:

```
config firewall policy
   edit 4
      set ntlm enable
      set ntlm-guest enable
   end
```

NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
   edit 4
      set ntlm enable
      set ntlm-guest enable
      set ntlm-enabled-browsers <user_agent_string>
   next
   end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include “MSIE”, “Mozilla” (which includes FireFox), and “Opera”.

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

Certificate authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users. See Configuring certificate-based authentication on page 526.

Certificates are also inherent to the HTTPS protocol, where the browser validates the server’s identity using certificates. A site certificate must be installed on the FortiGate unit and the corresponding Certificate Authority (CA) certificate installed in the web browser.

To force the use of HTTPS, go to **User & Device > Authentication > Settings** and select **Redirect HTTP Challenge to a Secure Channel (HTTPS)**.

Restricting number of concurrent user logons

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can disallow concurrent administrative access using the same administrator user name, but from a different IP address. This allows valid users to continue their legitimate work while limiting hackers' activity.

To disable concurrent administrator sessions - CLI:

```
config system global
   set admin-concurrent disable
end
```

VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1. Configure user accounts.
2. Create one or more user groups for SSL VPN users.
3. Enable SSL VPN.
4. Optionally, set inactivity and authentication timeouts.
5. Configure a security policy with the user groups you created for SSL VPN users.
   See FortiOS Handbook SSL VPN guide.

Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. The maximum time is 72 hours (259 200 seconds). For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
   set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See Configuring XAuth authentication.

To configure user group authentication for dialup IPsec - web-based manager:

1. Configure the dialup users who are permitted to use this VPN. Create a user group with Type:Firewall and add them to it.
   For more information, see Users and user groups on page 463
2. Go to **VPN > IPsec > Wizard**, select **Dialup**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select **Preshared Key** and enter the preshared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.

To configure user group authentication for dialup IPsec - CLI example:

The `peertype` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
   edit office_vpn
      set interface port1
      set type dynamic
      set psksecret yORRAzltNGhzgtV32jend
      set proposal 3des-sha1 aes128-sha1
      set peertype dialup
      set usrgrp Group1
   end
```

Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username

and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

To configure authentication for a dialup IPsec VPN - web-based manager:

1. Configure the users who are permitted to use this VPN. Create a user group and add the users to the group. For more information, see "Users and user groups" on page 463.
2. Go to **VPN > IPsec > Wizard**, select **Dialup**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select **Preshared Key** and enter the preshared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.
5. Go to **VPN > IPsec > Tunnels**, edit the Tunnel just created, select **Convert To Custom Tunnel**, and edit **XAUTH** as following:

Type	Select **PAP**, **CHAP**, or **AUTO**. Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
User Group	Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

6. Select **OK**.

For more information about XAUTH configuration, see the IPsec VPN chapter of the FortiOS Handbook.

To configure authentication for a dialup IPsec VPN - CLI example:

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
   edit office_vpn
      set interface port1
      set type dynamic
      set psksecret yORRAzltNGhzgtV32jend
      set proposal 3des-sha1 aes128-sha1
      set peertype dialup
      set xauthtype pap
      set usrgrp Group1
   end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the FortiOS Handbook IPsec VPN guide.

Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a security user group and add them to it. For more information, see Users and user groups on page 463.
2. Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
   set status enable
   set sip 192.168.0.100
   set eip 192.168.0.110
   set usrgrp PPTP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a L2TP VPN

1. Configure the users who are permitted to use this VPN. Create a user group and add them to it. For more information, see Users and user groups on page 463.
2. Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
   set status enable
   set sip 192.168.0.100
```

```
        set eip 192.168.0.110
        set usrgrp L2TP_Group
    end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- Introduction to Captive Portals
- Configuring a captive portal
- Customizing captive portal pages

Introduction to Captive Portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.

Configuring a captive portal

Captive portals are configured on network interfaces. On a physical (wired) network interface, you edit the interface configuration in **System > Network > Interfaces** and set **Security Mode** to **Captive Portal**. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **System > Network > Interfaces**.

To configure a wired Captive Portal - web-based manager:

1. Go to **System > Network > Interfaces** and edit the interface to which the users connect.
2. In **Security Mode** select **Captive Portal**.

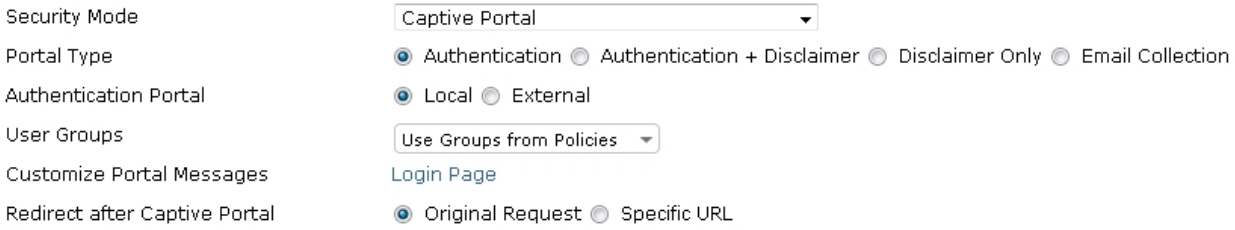
3. Enter

Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups or select **Use Groups from Policies**, which permits the groups specified in the security policy. **Use Groups from Policies** is not available in WiFi captive portals.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Enable, then select Edit. See Customizing captive portal pages on page 508.

4. Select **OK**.

To configure a WiFi Captive Portal - web-based manager:

1. Go to **WiFi Controller > WiFi Network > SSID** and create your SSID.
   If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **System > Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.



3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Introduction to Captive Portals on page 506.
Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.

User Groups	Select permitted user groups.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. See "Captive portals" on page 508.

4. Select **OK**.

Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
   edit r_exempt
      config rule
         edit 1
            set devices printer
         end
      end
```

Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

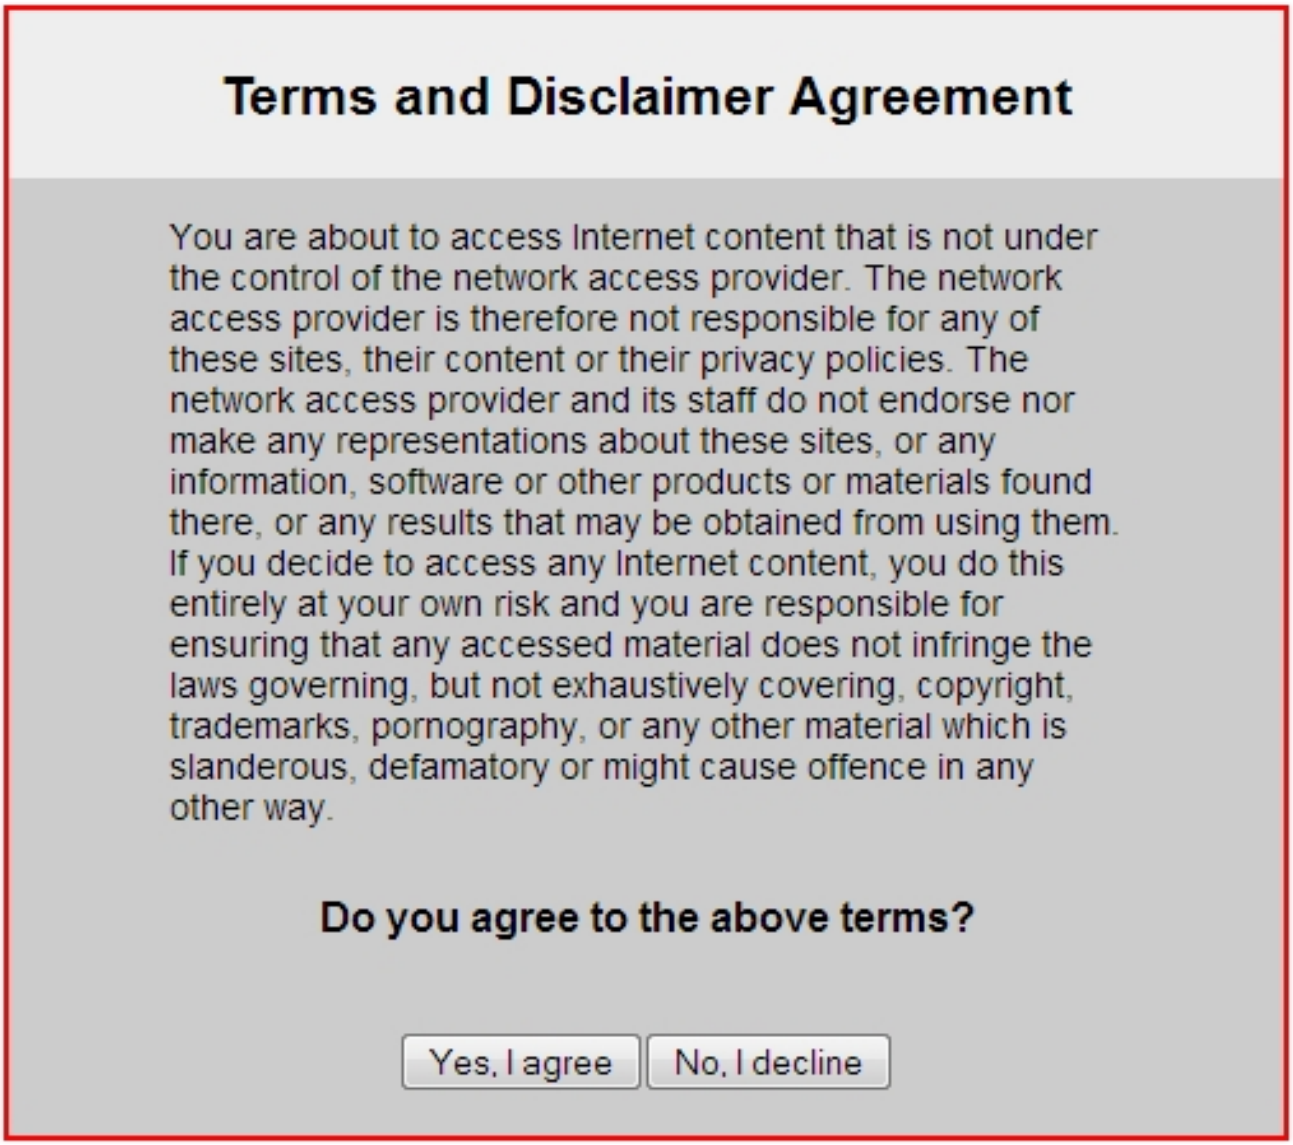
There is an exception to this rule. The line “Please enter your credentials to continue” is provided by the %%QUESTION%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line “Firewall authentication failed. Please try again.” is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.(WiFi or SSL VPN only)



- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file:

1. Go to **System > Config > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.
   The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

To specify the new logo in the replacement message:

1. Go to **System > Network > Interfaces** and edit the interface.
   The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
   - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
   - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.
   By default it specifies the Fortinet logo: `%%IMAGE:logo_fw_auth%%`
4. Change the image name to the one you provided for your logo.
   The tag should now read, for example, `%%IMAGE:mylogo%%`
5. Select **Save**.
6. Select **OK**.

Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

To modify portal page text

1. Go to **System > Network > Interfaces** and edit the interface.
   The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
   - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
   - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may `set security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
   edit "port1"
      set vdom "root"
      set ip 172.16.101.1 255.255.255.0
      set allowaccess ping https ssh snmp http
      set type physical
      set explicit-web-proxy enable
      set alias "LAN"
      set security-mode captive-portal
      set snmp-index 1
   next
end
```

Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

- What is a security certificate?
- Certificates overview
- Managing X.509 certificates
- Configuring certificate-based authentication
- Example — Generate a CSR on the FortiGate unit
- Example — Generate and Import CA certificate with private key pair on OpenSSL
- Example — Generate an SSL certificate in OpenSSL

What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the web site they where they are logging in.

A certificate includes identifying information such as the company and location information for the web site, as well as the third-party company name, the expiry date of the certificate, and the public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-to-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed below.

Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses: "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----"
.cer **.crt** **.der**	Security CERtificate	Usually binary DER form, but Base64-encoded certificates are common too.
.p7b **.p7c**		Structure without data, just certificates or CRLs. PKCS#7 is a standard for signing or encrypting (officially called "enveloping") data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected).
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

- Certificates and protocols
- IPsec VPNs and certificates
- Certificate types on the FortiGate unit

Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit's identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit's self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.

- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate.

For more information, see the FortiOS Handbook SSL VPN guide.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Secure Certificate Enrollment Protocol (SCEP), and Server-based Certificate Validation Protocol (SCVP).

Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OSCP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

Secure Certificate Enrollment Protocol

Secure Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

IPsec VPNs and certificates

Certificate authentication is a more secure alternative to preshared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it permits an IPsec tunnel to be established. See Authenticating IPsec VPN users with security certificates on page 527 .

Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at www.example.com (such as http://www.example.com/home/jsmith) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

For information about generating a certificate request, see Generating a certificate signing request on page 518. For information about installing a local certificate, see Obtaining and installing a signed server certificate from an external CA on page 521

Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list. You can select **Import** to install a certificate from the management PC.

CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of www.example.com instead of just the smaller single web page.

Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see Generating a certificate signing request on page 518.

Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser's documentation.

This section includes:

- Generating a certificate signing request
- Generating certificates with CA software
- Obtaining and installing a signed server certificate from an external CA
- Installing a CA root certificate and CRL to authenticate remote clients
- Troubleshooting certificates
- Online updates to certificates and CRLs
- Backing up and restoring local certificates

Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

To generate a certificate request in FortiOS - web-based manager:

1. Go to **System > Certificates > Local Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

4. Enter values in the **Subject Information** area to identify the FortiGate unit:
   - If the FortiGate unit has a static IP address, select **Host IP**and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.
   - If the FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select **Domain Name**, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an “unable to verify certificate” type message may be displayed in the user’s browser whenever the public IP address of the FortiGate unit changes.

   - If you select **E-Mail**, enter the email address of the owner of the FortiGate unit.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
Organization	Legal name of your company or organization.
Locality (City)	Name of the city or town where the FortiGate unit is installed.
State/Province	Name of the state or province where the FortiGate unit is installed.
Country	Select the country where the FortiGate unit is installed.
e-mail	Contact email address.
Subject Alternative Name	Optionally, enter one or more alternative names for which the certificate is also valid. Separate names with a comma. A name can be: • e-mail address • IP address • URI • DNS name (alternatives to the Common Name) • directory name (alternatives to the Distinguished Name) You must precede the name with the name type. Examples: IP:1.1.1.1 email:test@fortinet.com email:my@other.address URI:http://my.url.here/

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. From the **Key Size** list, select **1024 Bit**, **1536 Bit**, **2048 Bit** or **secp256r1**, **secp384r1**, **secp521r1** respectively. Larger keys are slower to generate but more secure.
8. In **Enrollment Method**, you have two methods to choose from. Select **File Based** to generate the certificate request, or **Online SCEP** to obtain a signed SCEP-based certificate automatically over the network. For the SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.
9. Select **OK**.
10. The request is generated and displayed in the **Local Certificates** list with a status of `PENDING`.
11. Select the **Download** button to download the request to the management computer.
12. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
13. Name the file and save it on the local file system of the management computer.

The certificate request is ready for the certificate authority to be signed.

Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include ssl-ca from OpenSSL (available for Linux, Windows, and Mac) or gensslcert from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See Example — Generate and Import CA certificate with private key pair on OpenSSL on page 529.

The general steps for generating certificates with CA software are

1. Install the CA software as a stand-alone root CA.
2. Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

Server certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension
4. Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

CA certificate

1. Retrieve the CA Certificate from the CA software as a DER encoded file.
2. Import the CA certificate file to the FortiGate unit at **System > Certificates > Import > CA Certificates**.

PKI certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.

2. Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension.
4. Install the certificate in the user's web browser or IPsec VPN client as needed.

Obtaining and installing a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

To submit the certificate signing request (file-based enrollment):

1. Using the web browser on the management computer, browse to the CA web site.
2. Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.
3. Follow the CA instructions to download their root certificate and CRL.
   When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

To install or import the signed server certificate - web-based manager

1. On the FortiGate unit, go to **System > Certificates > Import > Local Certificates**.
2. From **Type**, select **Local Certificate**.
3. Select **Browse**, browse to the location on the management computer where the certificate was saved, select the certificate, and then select **Open**.
4. Select **OK**, and then select **Return**.

Installing a CA root certificate and CRL to authenticate remote clients

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

To install a CA root certificate

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to **System > Certificates > Import > CA Certificates**.
3. Do one of the following:
   - To import using SCEP, select **SCEP**. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
   - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the certificate has been saved. Select the certificate, and then select **Open**.
5. Select **OK**, and then select **Return**.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA_Cert_1, CA_Cert_2, CA_Cert_3, and so on).

To import a certificate revocation list

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. The CRL has an “effective date” and a “next update” date. The interval is typically 7 days (for Microsoft CA). FortiOS will update the CRL automatically. Also, there is a CLI command to specify an “update-interval” in seconds. Recommendation should be 24 hours (86400 seconds) but depends on company security policy.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to **System > Certificates > Import > CRL**.
3. Do one of the following:
   - To import using an HTTP server, select **HTTP** and enter the URL of the HTTP server.
   - To import using an LDAP server see this KB article.
   - To import using an SCEP server, select **SCEP** and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
   - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the CRL has been saved. Select the CRL and then select **Open**.
5. Select **OK**, and then select **Return**.

Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can’t be found. Often the problem is with a third party web site, and not FortiOS. However, some problems can be traced back to FortiOS such as DNS or routing issues.

Certificate is reported as expired when it is not

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the “best before” date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server’s clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer believes a certificate was either stolen or misused. Its possible it is due to reasons on the issuer’s side, such as a system change or such. In either case it is best to contact the certificate issuer to determine what is happening and why.

A secure connection cannot be completed (Certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securely to a web site, that web site will present its valid certificate to prove their identity is valid. When the web site's certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this web site without problems, this error could mean that someone is trying to impersonate or hijack the web site, and best practices dictates you not continue.

Reasons a web site's certificate cannot be validated include:

- The web site uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of the web site using some other method before you accept the certificate.
- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com` that is not valid for `marketing.example.com`. If you encounter this problem, contact the webmaster for the web site to inform them of the problem.
- There is a DNS or routing problem. If the web site's certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verify the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the web site allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 (SSH).

Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

Local certificates

In the `config vpn certificate local` command, you can specify automatic certificate renewal. The relevant fields are:

`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS. The following options appear after you add the `<URL_str>`.
`scep-password <password_str>`	The password for the SCEP server.
`auto-regenerate-days <days_int>`	How many days before expiry the FortiGate unit requests an updated local certificate. The default is `0`, no auto-update.
`auto-regenerate-days-warning <days_int>`	How many days before local certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
   edit mycert
      set scep-url http://scep.example.com/scep
      set scep-server-password my_pass_123
      set auto-regenerate-days 3
```

```
      set auto-regenerate-days-warning 2
   end
```

CA certificates

In the `config vpn certificate ca` command, you can specify automatic certificate renewal. The relevant fields are:

Variable	Description
`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS.
`auto-update-days <days_int>`	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is `0`, no auto-update.
`auto-update-days-warning <days_int>`	How many days before CA certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
   edit mycert
      set scep-url http://scep.example.com/scep
      set auto-update-days 3
      set auto-update-days-warning 2
   end
```

Certificate Revocation Lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
`http-url <http_url>`	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`scep-cert <scep_certificate>`	Local certificate used for SCEP communication for CRL auto-update.
`scep-url <scep_url>`	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`update-interval <seconds>`	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter `0` to update the CRL only when it expires. Not available for http URLs.
`update-vdom <update_vdom>`	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
   edit cert_crl
```

```
    set http-url http://scep.example.com/scep
    set scep-cert my-scep-cert
    set scep-url http://scep.ca.example.com/scep
    set update-interval 0
    set update-vdom root
end
```

Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the **System > Certificates** page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the **System Information** widget on the Dashboard of the web-based manager. Look for **[Backup]** and **[Restore]** in the **System Configuration** row. The backup file is created in a FortiGate-proprietary format.

To export a server certificate and private key - CLI:

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

   ```
   execute vpn certificate local export tftp <cert_name> <exp_filename> <tftp_ip>
       <password>
   ```

   where:

   - `<cert_name>` is the name of the server certificate; typing `?` displays a list of installed server certificates.
   - `<exp_filename>` is a name for the output file.
   - `<tftp_ip>` is the IP address assigned to the TFTP server host interface.
3. Move the output file from the TFTP server location to the management computer for future reference.

To import a server certificate and private key - web-based manager:

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **PKCS12 Certificate**.
3. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file, and then select **Open**.
4. In the **Password** field, type the password needed to upload the exported file.
5. Select **OK**, and then select **Return**.

To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **Certificate**.

3. Select the **Browse** button beside the **Certificate file** field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select **Open**.
4. Select the **Browse** button beside the **Key file** field. Browse to the location on the management computer where the key file has been saved, select the file, and then select **Open**.
5. If required, in the **Password** field, type the associated password, and then select **OK**.
6. Select **Return**.

Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certificates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match. Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see Installing a CA root certificate and CRL to authenticate remote clients on page 521).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select **PKI** as the account **Type** and select the **User Group** to which the administrator belongs.

Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

To enable certificate authentication for an SSL VPN user group:

1. Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2. Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.
3. Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see Installing a CA root certificate and CRL to authenticate remote clients on page 521).
4. Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6. Go to **Policy & Objects > Policy > IPv4**.
7. Edit the SSL-VPN security policy.
8. Select the user group created earlier in the **Source User(s)** field.
9. Select **OK**.

Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

To enable the FortiGate unit to authenticate itself with a certificate:

1. Install a signed server certificate on the FortiGate unit.
   See To install or import the signed server certificate - web-based manager on page 521.
2. Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see To install a CA root certificate on page 521.
3. Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see To import a certificate revocation list on page 522.
4. In the VPN phase 1 configuration, set **Authentication Method** to **Signature** and from the **Certificate Name** list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can be multiple peers.

To configure certificate authentication of a single peer

1. Install the CA root certificate and CRL.
2. Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. In the VPN phase 1 **Peer Options**, select **peer certificate** for **Accept Types** field and select the PKI user that you created in the **Peer certificate** field.

To configure certificate authentication of multiple peers (dialup VPN)

1. Install the corresponding CA root certificate and CRL.
2. Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 **Peer Options**, select **peer certificate group** for **Accept Types** field and select the PKI user group that you created in the **Peer certificate group** field.

Example — Generate a CSR on the FortiGate unit

This example follows all the steps required to create and install a local certificate on the FortiGate unit, without using CA software.

The FortiGate unit is called myFortiGate60, and is located at 10.11.101.101 (a private IP address) and http://myfortigate.example.com. Mr. John Smith (john.smith@myfortigate.example.com) is the IT administrator for this FortiGate unit, and the unit belongs to the Sales department located in Greenwich, London, England.

To generate a certificate request on the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter `myFortiGate60`.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Since the IP address is private, we will use the FQDN instead.

4. Select **Domain Name**, and enter `http://myfortigate.example.com`.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Sales
Organization	Example.com
Locality (City)	Greenwich
State/Province	London
Country	England
e-mail	john.smith@myfortigate.example.com

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. If RSA is selected, from the **Key Size** list, select **2048 Bit**. If Elliptic Curve is selected,from the **Curve Name** list, select **secp256r1**.
8. In **Enrollment Method**, select **File Based** to generate the certificate request

9. Select **OK**.
   The request is generated and displayed in the **Local Certificates** list with a status of PENDING.
10. Select the **Download** button to download the request to the management computer.
11. In the **File Download** dialog box, select ***Save*** and save the Certificate Signing Request on the local file system of the management computer.
12. Name the file and save it on the local file system of the management computer.

Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is: http://www.slproweb.com/products/Win32OpenSSL.html.

Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

To generate the private key and certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the command:
   ```
   cd c:\OpenSSL-Win32\bin
   ```
2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.
   ```
   openssl genrsa -des3 -out fgtcapriv.key 2048
   ```
   This command generates an RSA DES3 2048-bit encryption key.
3. The following command will generate the certificate using the key from the previous step.
   ```
   openssl req -new -x509 -days 3650 -extensions v3_ca -key fgtcapriv.key -out
       fgtca.crt
   ```
   This step generates an X509 CA certificate good for 10 years that uses the key generated in the previous step. The certificate filename is `fgtca.crt`.

   You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

To import the certificate to the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
   Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.

6. For **Password**, enter the PEM Pass Phrase you entered earlier, such as fortinet123.
7. Select **OK**.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`.You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a .CER file.

It can now be used in Authenticating IPsec VPN users with security certificates on page 527, and Authenticating SSL VPN users with security certificates on page 526.

Optionally, you can install the certificate as a CA Certificate. CA certificates are used in HTTPS proxy/inspection. To do this, under **System > Certificates** select **Import > CA Certificate**. Select **Local PC** and enter the certificate file `c:\OpenSSL-Win32\bin\fgtca.crt`. Then select **OK**. This certificate will be displayed in the CA Certificate list under the name `CA_Cert_1`.

Example — Generate an SSL certificate in OpenSSL

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

In this example, you will:

- Generate a CA signed SSL certificate
- Generate a self-signed SSL certificate
- Import the SSL certificate into FortiOS

Assumptions

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating a CA signed SSL certificate

This procedure assumes that you have already completed Example — Generate and Import CA certificate with private key pair on OpenSSL on page 529 successfully.

To generate the CA signed SSL certificate:

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:
   ```
   cd c:\OpenSSL-Win32\bin
   ```
2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.
   ```
   openssl genrsa -des3 -out fgtssl.key 2048
   ```
   This command generates an RSA DES3 2048-bit encryption key.
3. Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — To generate the private key and certificate. You can leave the Challenge Password blank.
   ```
   openssl req -new -key fgtssl.key -out fgtssl.csr
   ```
4. Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in Example — Generate and Import CA certificate with private key pair on OpenSSL.

```
openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -CAkey fgtcapriv.key -set_
    serial 01 -out fgtssl.crt
```

This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt.

Generating a self-signed SSL certificate

This procedures does not require any existing certificates.

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:
   ```
   cd c:\OpenSSL-Win32\bin
   ```
2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.
   ```
   openssl genrsa -des3 -out fgtssl.key 2048
   openssl req -new -key fgtssl.key -out fgtssl.csr
   openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key -out fgtssl.crt
   ```
   These commands:
   - generate an RSA 3DES 2048-bit private key,
   - generate an SSL certificate signing request, and
   - sign the CSR to generate an SSL .CRT certificate file.

Import the SSL certificate into FortiOS

To import the certificate to FortiOS- web-based manager

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
   Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.
6. For **Password**, enter the PEM Pass Phrase you entered, such as fortinet.
7. Select **OK**.

The SSL certificate you just uploaded can be found under **System > Certificates** under the name of the file you uploaded — `fgtssl`.

To confirm the certificate is uploaded properly - CLI:

```
config vpn certificate local
   edit fgtssl
      get
   end
```

The get command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

To use the new SSL certificate - CLI

```
config vpn ssl settings
   set servercert fgtssl
```

```
end
```

This assigns the fgtssl certificate as the SSL server certificate. For more information see the FortiOS Handbook SSL VPN guide.

Single Sign-On using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent,

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

The FortiAuthenticator unit can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit.

User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget, like this:

	User not logged in. Click **Login** to go to the FortiAuthenticator login page.
	User logged in. Name displayed. **Logout** button available.

The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login timeout expires, which can be up to 30 days.

Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

The user simply accesses resources and all authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deauthenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to **Fortinet SSO Methods > SSO > Portal Services** to do this. Copy the **Embeddable login widget** code for use on your organization's

home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

FortiClient SSO Mobility Agent

Your users must be running at least FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to select **Enable FortiClient SSO Mobility Agent Service**, optionally select **Enable Authentication** and choose a **Secret key**. Go to **Fortinet SSO Methods > SSO > General**. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers. See Configuring the FortiGate unit on page 534.

Configuring the FortiAuthenticator unit

The FortiAuthenticator unit can poll FortiGate units, Windows Active Directory, RADIUS servers, LDAP servers, and FortiClients for information about user logon activity.

To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave the Listening port at 8000, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall.
   Optionally, you can set the Login Expiry time. This is the length of time users can remain logged in before the system logs them off automatically. The default is 480 minutes (8 hours).
3. Select **Enable Authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter

Enable Windows Active Directory domain controllers	Select for integration with Windows Active Directory.
Enable Radius accounting SSO clients	Select if you want to use a Remote Radius server.
Enable Syslog SSO	Select for integration with Syslog server.
Enable FortiClient SSO Mobility Agent service **Enable Authentication**	Select both options to enable single sign-on by clients running FortiClient Endpoint Security. Enter the **Secret key**. Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.

5. Select **OK**.

For more information, see the FortiAuthenticator Administration Guide.

Configuring the FortiGate unit

Adding a FortiAuthenticator unit as an SSO agent

On the FortiGate unit, you need to add the FortiAuthenticator unit as a Single Sign-On agent that provides user logon information.

To add a FortiAuthenticator unit as SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the FortiAuthenticator unit.
4. In Primary Agent IP/Name, enter the IP address of the FortiAuthenticator unit.
5. In Password, enter the secret key that you defined for the FortiAuthenticator unit.
   On the FortiAuthenticator unit, you go to **Fortinet SSO Methods > SSO > General** to define the secret key.
   Select **Enable Authentication**.
6. Select **OK**.

In a few minutes, the FortiGate unit receives a list of user groups from the FortiAuthenticator unit. The entry in the Single Sign-On server list shows a blue caret.

When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

Configuring an FSSO user group

You cannot use FortiAuthenticator SSO user groups directly in a security policy. Create an FSSO user group and add FortiAuthenticator SSO user groups to it. FortiGate FSSO user groups are available for selection in identity-based security policies.

To create an FSSO user group:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In Type, select **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**.
   The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

Configuring security policies

You can create identity-based policies based on FSSO groups as you do for local user groups. For more information about security policies see the Firewall chapter.

Configuring the FortiClient SSO Mobility Agent

The user's device must have at least FortiClient Endpoint Security v5.0 installed. Only two pieces of information are required to set up the SSO Mobility Agent feature: the FortiAuthenticator unit IP address and the preshared secret.

The user needs to know the FortiAuthenticator IP address and preshared secret to set up the SSO Mobility Agent. Or, you could preconfigure FortiClient.

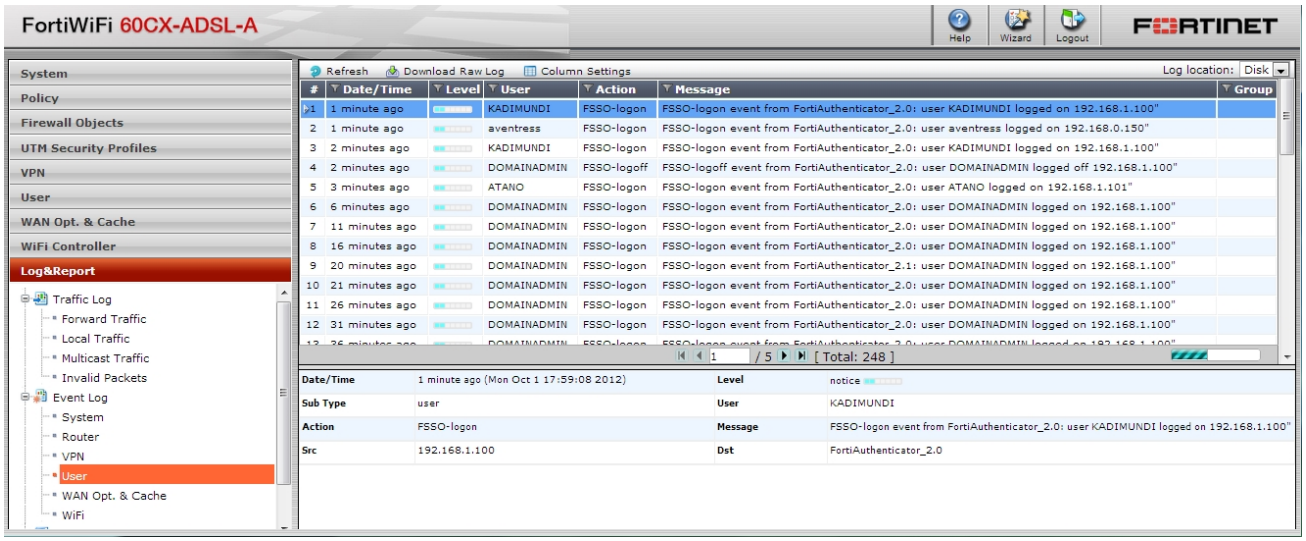
To configure FortiClient SSO Mobility Agent:

1. In FortiClient Endpoint Security, go to **File > Settings**.
   You must run the FortiClient application as an administrator to access these settings.
2. Select **Enable single sign-on mobility agent**. Enter the FortiAuthenticator unit IP address, including the listening port number specified on the FortiAuthenticator unit.
   Example: 192.168.0.99:8001. You can omit the port number if it is 8005.
3. Enter the preshared key.
4. Select **OK**.

Viewing SSO authentication events on the FortiGate unit

User authentication events are logged in the FortiGate event log.

Go to **Log & Report > Event Log > User**.



Single Sign-On to Windows AD

The FortiGate unit can authenticate users transparently and allow them network access based on their privileges in Windows AD. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term “Single Sign-On”.

The following topics are included:

- Introduction to Single Sign-On with Windows AD
- Configuring Single Sign On to Windows AD
- FortiOS FSSO log messages
- Testing FSSO
- Troubleshooting FSSO

Introduction to Single Sign-On with Windows AD

Introduced in FortiOS 5.0, Single Sign-On (SSO) support provided by FortiGate polling of domain controllers is simpler than the earlier method that relies on agent software installed on Windows AD network servers. No Fortinet software needs to be installed on the Windows network. The FortiGate unit needs access only to the Windows AD global catalog and event log.

When a Windows AD user logs on at a workstation in a monitored domain, the FortiGate unit

- detects the logon event in the domain controller’s event log and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses the domain controller’s LDAP server to determine which groups the user belongs to,
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consist of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

Configuring Single Sign On to Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate unit.

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Windows AD global catalog. See Configuring LDAP server access on page 538.
- Configure the LDAP Server as a Single Sign-On server. See Configuring the LDAP Server as a Single Sign-On server on page 539.

- Add Active Directory user groups to FortiGate FSSO user groups. See Creating Fortinet Single Sign-On (FSSO) user groups on page 540.
- Create security policies for FSSO-authenticated groups. See Creating security policies on page 540.
- Optionally, specify a guest protection profile to allow guest access. See Enabling guest access through FSSO security policies on page 542

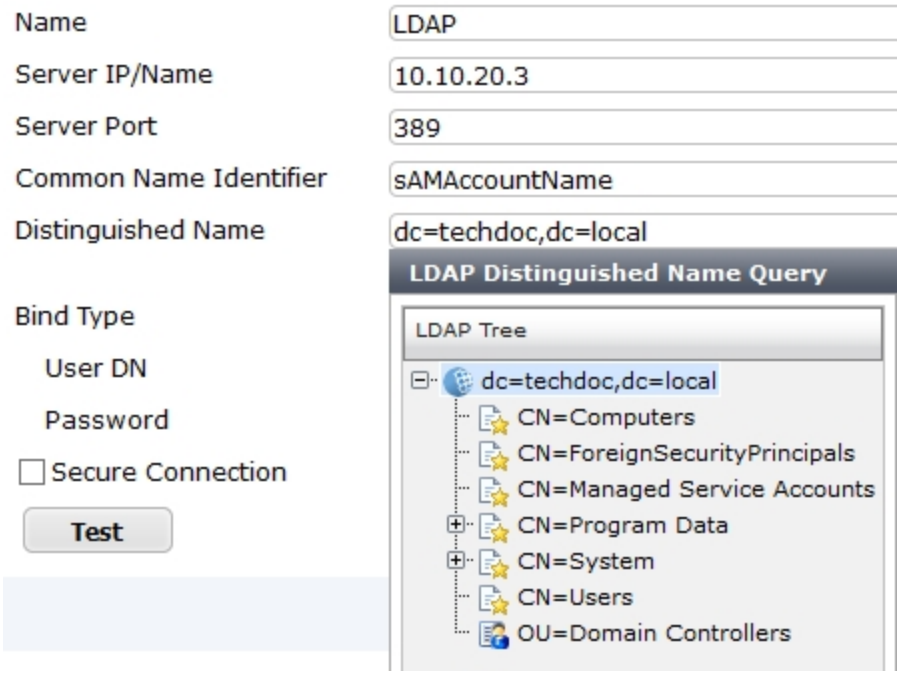
Configuring LDAP server access

The FortiGate unit needs access to the domain controller's LDAP server to retrieve user group information.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration (in **User & Device > Authentication > LDAP Servers**) includes a function to preview the LDAP server's response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

To add an LDAP server - web-based manager:

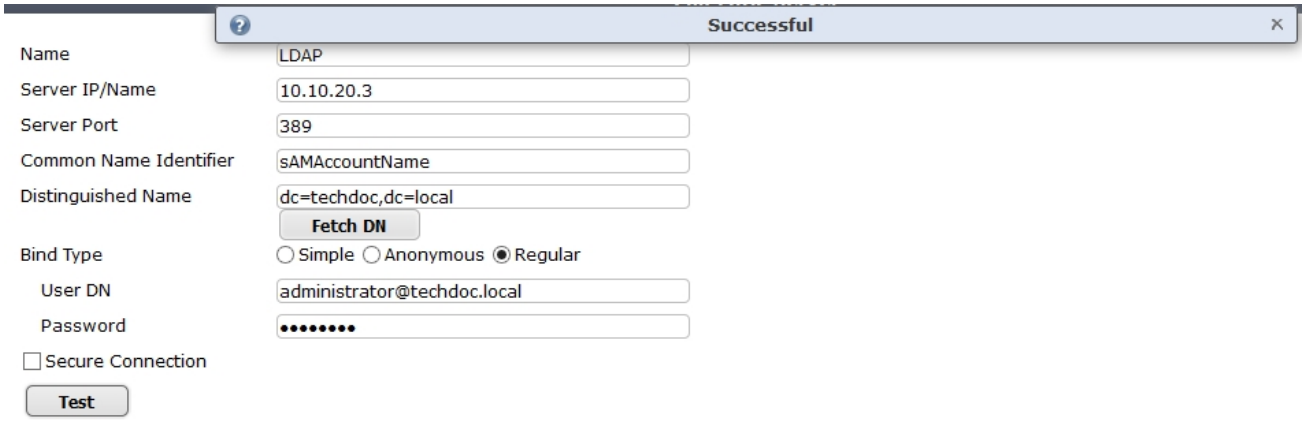
1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**.The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is dc=techdoc,dc=local
5. Select **Fetch DN**, this will fetch the Windows AD directory.



6. Set **Bind Type** to **Regular.**
7. In the **User DN** field, enter the administrative account name that you created for FSSO.
   For example, if the account is administrator, enter "administrator@techdoc.local".

8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
   - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
   - In the **Certificate** field, select the appropriate certificate for authentication.

   Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.



To configure LDAP for FSSO - CLI example:

```
config user ldap
   edit LDAP
      set server 10.10.20.3
      set cnid sAMAccountName
      set dn dc=techdoc,dc=local
      set type regular
      set username administrator@techdoc.local
      set password <your_password>
   next
end
```

Configuring the LDAP Server as a Single Sign-On server

The LDAP server must be added to the FortiGate Single Sign-On configuration.

To add the LDAP server as a Single Sign-On server:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. Enter

Type	Poll Active Directory Server
Server IP/Name	Server Name or IP address of the Domain Controller
User	A Domain user name
Password	The user's password

LDAP Server	Select the LDAP server you added earlier.
Enable Polling	Select

3. Select **OK**.

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
   The **New User Group** dialog box opens.
2. In the **Name** box, enter a name for the group, FSSO_Internet_users for example.
3. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
4. In **Members**, select the required **FSSO** groups.
5. Select **OK**.

To create the FSSO_Internet-users user group - CLI

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
   end
```

Default FSSO group

`SSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have an FSSO account to authenticate and have access to network resources. See Enabling guest access through FSSO security policies on page 542.

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > Policy > IP4** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	`fsso_group`
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select **Security Events**.

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr company_network
      set dstaddr all
      set action accept
      set groups fsso_group
      set schedule always
      set service HTTP HTTPS FTP TELNET
      set nat enable
   end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to Windows AD and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and UTM profiles that apply to guest users — typically guests have access to a reduced set of services. See Creating security policies on page 540.

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see Enabling security logging on page 498. For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events needed, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged.

To enable event logging:

1. Go to **Log&Report > Log Config > Log Settings**.
2. In **Event Logging**, select

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Select **Apply**.

List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful

Message ID	Severity	Description
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see Troubleshooting FSSO on page 543.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:`diagnose debug authd fsso list`
4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
IP: 192.168.1.240 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
Total number of users logged on: 2
----end of FSSO logons----
```

   The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name Connection Status
     ----------- -----------------
     SBS-2003 connected
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP).
- Ensure there is at least 64kbps bandwidth between the FortiGate unit and domain controllers. If there is insufficient bandwidth, some FSSO information might not reach the FortiGate unit. The best solution is to configure traffic shaping between the FortiGate unit and the domain controllers to ensure that the minimum bandwidth is always available.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don’t have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Agent-based FSSO

FortiOS can provide single sign-on capabilities to Windows AD, Citrix, or Novell eDirectory users with the help of agent software installed on these networks. The agent software sends information about user logons to the FortiGate unit. With user information such as IP address and user group memberships from the network, FortiGate security policies can allow authenticated network access to users who belong to the appropriate user groups without requesting their credentials again.

For Windows AD networks, FortiGate units can provide SSO capability without agent software by directly polling the Windows AD domain controllers. For information about this type of SSO, seeSingle Sign-On to Windows AD on page 537.

The following topics are included:

- Introduction to agent-based FSSO
- FSSO NTLM authentication support
- Agent installation
- Configuring the FSSO Collector agent for Windows AD
- Configuring the FSSO TS agent for Citrix
- Configuring FSSO with Novell networks
- Configuring FSSO Advanced Settings
- Configuring FSSO on FortiGate units
- FortiOS FSSO log messages
- Testing FSSO
- Troubleshooting FSSO

Introduction to agent-based FSSO

Fortinet Single Sign-On (FSSO), through agents installed on the network, monitors user logons and passes that information to the FortiGate unit. When a user logs on at a workstation in a monitored domain, FSSO

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- determines which user groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

FSSO can also provide NTLM authentication service for requests coming from FortiGate. SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support. See FSSO NTLM authentication support on page 551.

Introduction to FSSO agents

There are several different FSSO agents that can be used in an FSSO implementation:

- Domain Controller (DC) agent
- eDirectory agent
- Citrix/Terminal Server (TS) agent
- Collector (CA) agent

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

Domain Controller (DC) agent

The Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode. See FSSO for Windows AD on page 547.

eDirectory agent

The eDirectory agent is installed on a Novell network to monitor user logons and send the required information to the FortiGate unit. It functions much like the Collector agent on a Windows AD domain controller.The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.

Citrix/Terminal Server (TS) agent

The Citrix/Terminal Server (TS) agent is installed on a Citrix terminal server to monitor user logons in real time. It functions much like the DC Agent on a Windows AD domain controller.

Collector (CA) agent

This agent is installed as a service on a server in the Windows AD network to monitor user logons and send the required information to the FortiGate unit. The Collector agent can collect information from

- Domain Controller agent (Windows AD)
- TS agent (Citrix Terminal Server)

In a Windows AD network, the Collector agent can optionally obtain logon information by polling the AD domain controllers. In this case, DC agents are not needed.

The Collector can obtain user group information from the DC agent or optionally, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).

On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Collector agents installed. See FSSO NTLM authentication support on page 551.

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See Configuring FSSO on FortiGate units on page 579.

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

A FortiAuthenticator unit can act much like a Collector agent, collecting Windows AD user logon information and sending it to the FortiGate unit. It is particularly useful in large installations with several FortiGate units. For more information, see the FortiAuthenticator Administration Guide.

FSSO for Windows AD

FSSO for Windows AD requires at least one Collector agent. Domain Controller agents may also be required depending on the Collector agent working mode. There are two working modes to monitor user logon activity: DC Agent mode or Polling mode.

Collector agent DC Agent mode versus Polling mode

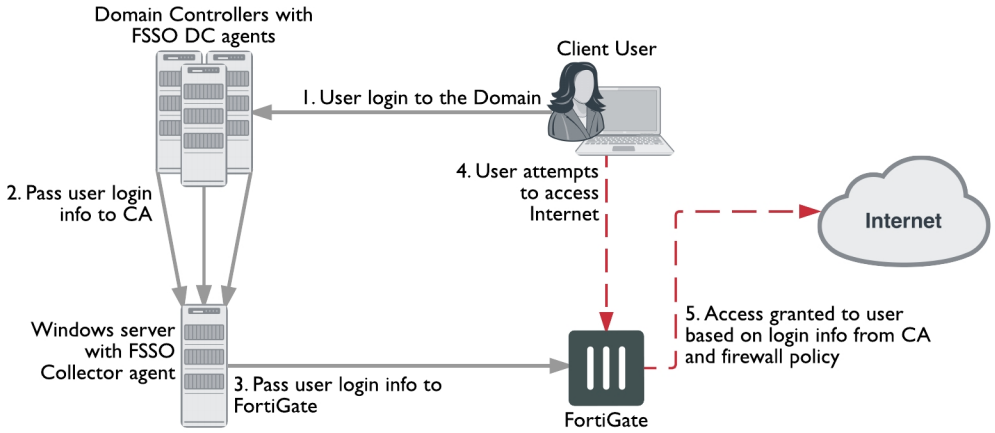
	DC Agent mode	Polling Mode
Installation	Complex — Multiple installations: one agent per DC plus Collector agent, requires a reboot	Easy — Only Collector agent installation, no reboot required
Resources	Shares resources with DC system	Has own resources
Network load	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
Level of Confidence	Captures all logons	Potential to miss a login if polling period is too great

DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode, a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

FSSO in DC agent mode



DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

Polling mode

In Polling mode there are three options — NetAPI polling, Event log polling, and Event log using WMI. All share the advantages of being transparent and agentless.

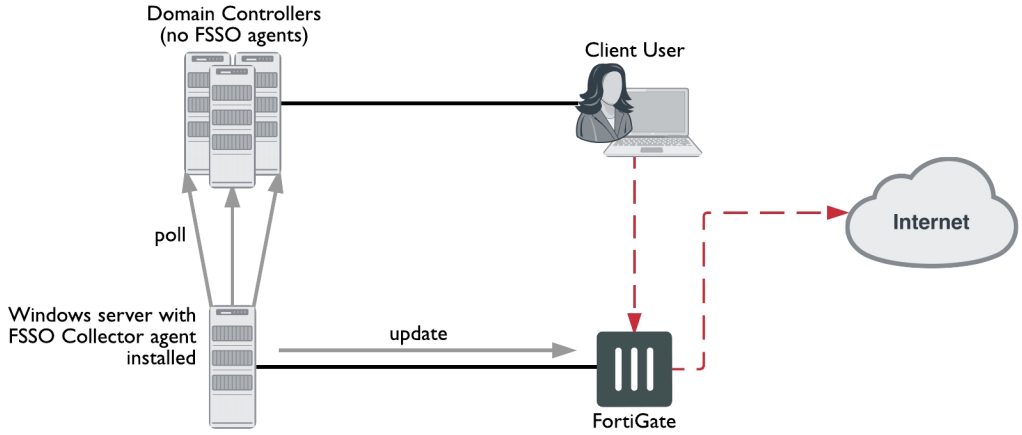
NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit on NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

Event log using WMI polling: WMI is a Windows API to get system information from a Windows server, CA is a WMI client and sends WMI queries for user logon events to DC, which in this case is a WMI server. Main advantage in this mode is that CA does not need to search security event logs on DC for user logon events, instead, DC returns all requested logon events via WMI. This also reduces network load between CA and DC.

In Polling mode, the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

FSSO in Polling mode



A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI.

Collector agent AD Access mode - Standard versus Advanced

The Collector agent has two ways to access Active Directory user information. The main difference between Standard and Advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices suggest you set up FSSO in Standard mode. This mode is easier to set up, and is usually easier to maintain and troubleshoot.

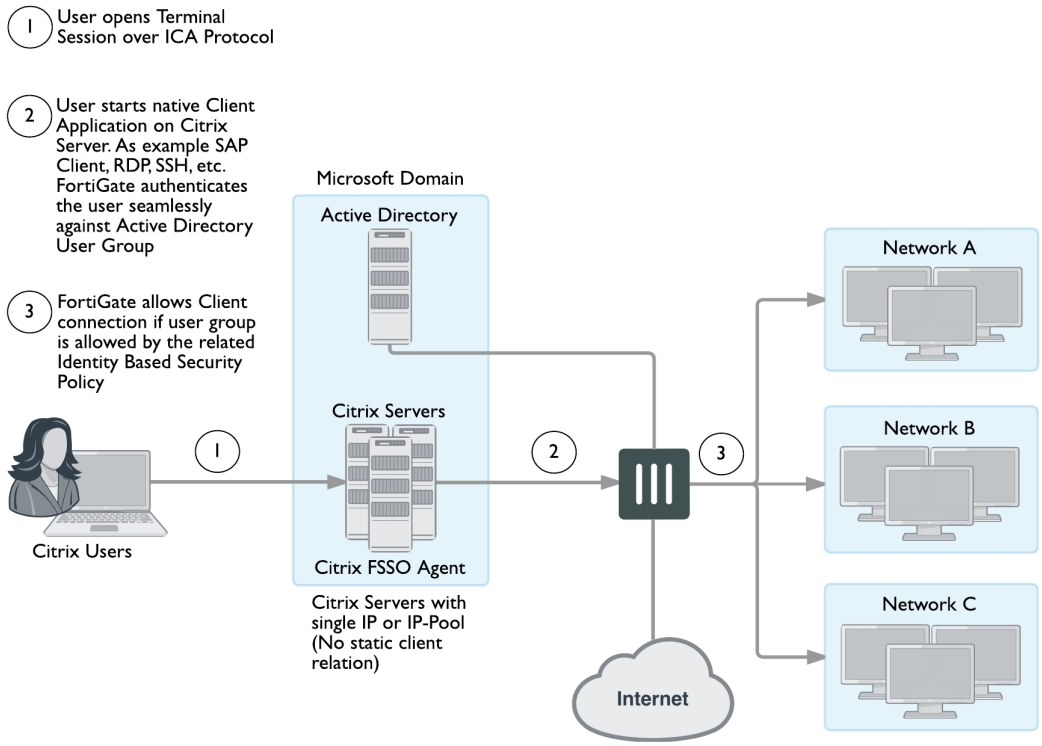
Standard and advanced modes have the same level of functionality with the following exceptions:

- Users have to create Group filters on the Collector agent. This differs from Advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
- Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

FSSO for Citrix

Citrix users can enjoy a similar Single Sign-On experience as Windows AD users. The FSSO TS agent installed on each Citrix server provides user logon information to the FSSO Collector agent on the network. The FortiGate unit uses this information to authenticate the user in security policies.

Citrix SSO topology



Citrix users do not have unique IP addresses. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

FSSO for Novell eDirectory

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards the information to the FortiGate unit. There is no need for the Collector agent.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system.

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

FSSO security issues

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server.

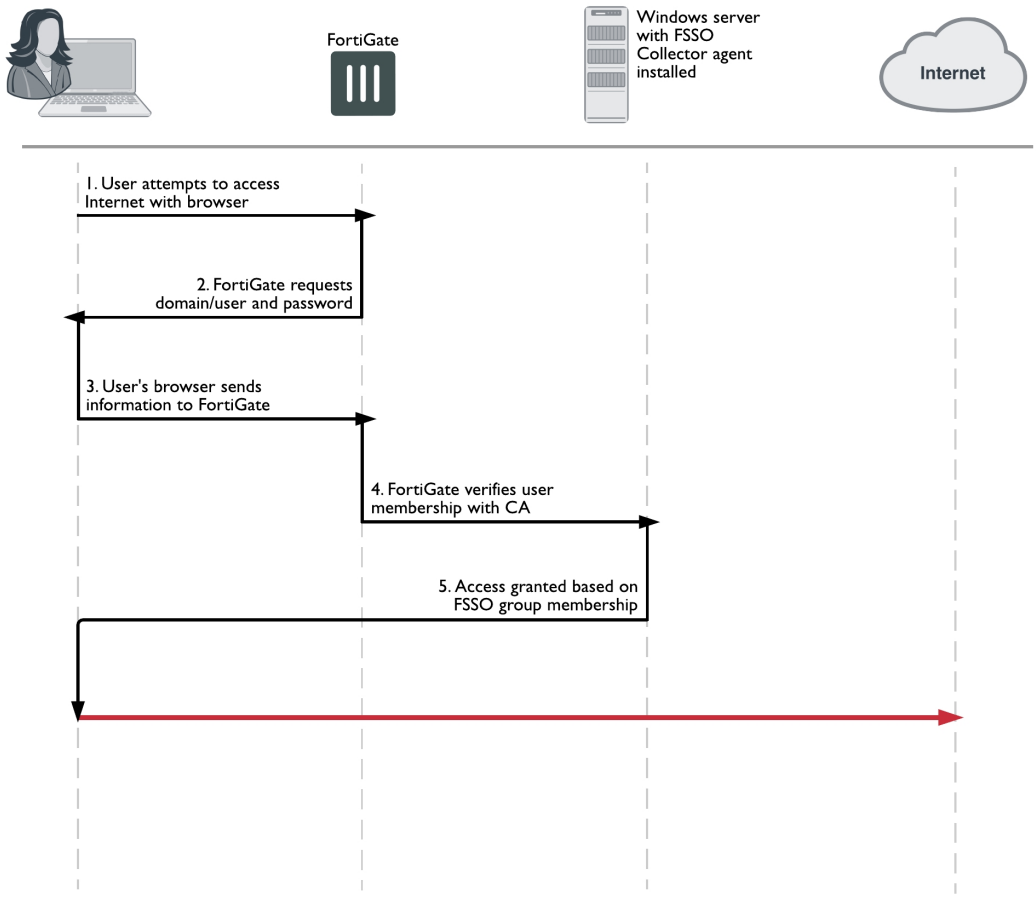
FSSO NTLM authentication support

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user's web browser must support NTLM.

The NTLM protocol protects the user's password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

NTLM authentication



If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection but will require authentication again in the future when the current authentication expires.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

NTLM in a multiple domain environment

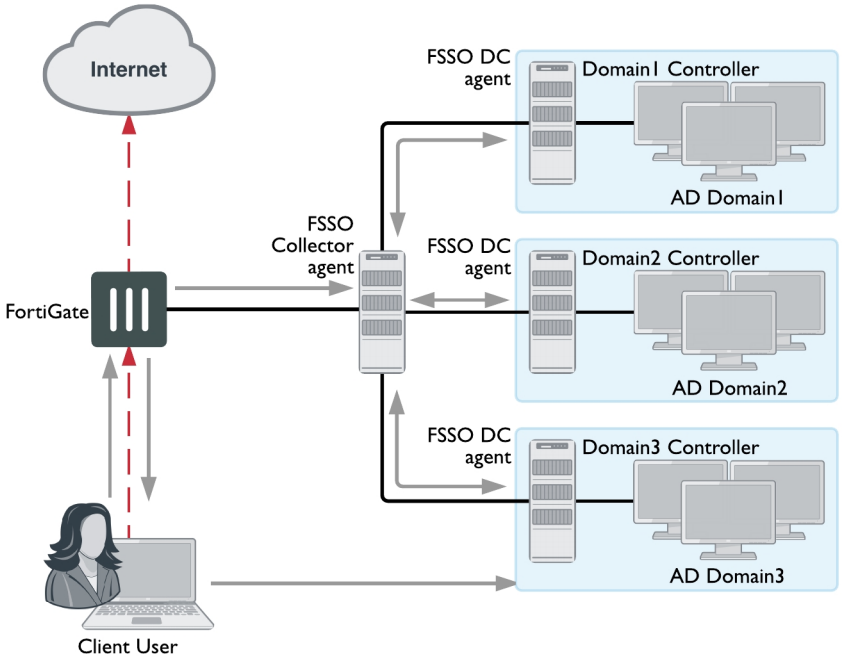
In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In the figure below, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each

with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

FSSO NTLM with multiple domains not in a forest



Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a `401 Unauthenticated` status code, and tells the client which authentication method to reply with in the header: `Proxy-Authenticated: NTLM`. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a `Proxy-Authorization: NTLM <negotiate string>` header. `<negotiate-string>` is a base64-encoded NTLM Type 1 negotiation packet.
4. The FortiGate unit replies with a `401 "proxy auth required"` status code, and a `Proxy-Authenticate: NTLM <challenge string>` (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: `Proxy-Authenticate: NTLM <authenticate string>`, where `<authenticate string>` is a NTLM Type 3 Authentication packet that contains:

- username and domain
- the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).

6. If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed, Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

Agent installation

After reading the appropriate sections of Introduction to agent-based FSSO on page 545 to determine which FSSO agents you need, you can proceed to perform the necessary installations.

Ensure you have administrative rights on the servers where you are installing FSSO agents. It is best practice to install FSSO agents using the built-in local administrator account. Optionally, you can install FSSO without an admin account. See Installing FSSO without using an administrator account on page 556.

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality.Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

Collector agent installation

To install FSSO, you must obtain the FSSO_Setup file from the Fortinet Support web site. This is available as either an executable (.exe) or a Microsoft Installer (.msi) file. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also installs the DC Agent on all of the domain controllers in your network.

To install the Collector agent:

1. Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.
   To use a non-admin read only account, see Installing FSSO without using an administrator account on page 556.
2. Log on to the account that you created in Step 1.
3. Double-click the `FSSOSetup.exe` file.
   The Fortinet SSO Collector Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Optionally, change the **User Name**.
8. By default, the agent is installed using the currently running account. If you want FSSO to use another existing admin account, change the **User Name** using the format DomainName \ UserName. For example if the account is `jsmith` and the domain is **example_corp** you would enter `example_corp\jsmith`.
9. In the **Password** field, enter the password for the account listed in the **User Name** field.
10. Select **Next**.
11. Enable as needed:
    - Monitor user logon events and send the information to the FortiGate unit
    - Serve NTLM authentication requests coming from FortiGate
      By default, both methods are enabled. You can change these options after installation.
12. Select the access method to use for Windows Directory:
13. Select **Standard** to use Windows domain and username credentials.
14. Select **Advanced** if you will set up LDAP access to Windows Directory.
    See Collector agent AD Access mode - Standard versus Advanced on page 549.
15. Select **Next** and then select **Install**.
    If you want to use DC Agent mode, ensure that **Launch DC Agent Install Wizard** is selected. This will start DC agent installation immediately after you select **Finish**.
16. Select **Finish**.

If you see an error such as Service Fortinet Single Sign On agent (service_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

DC agent installation

The FSSO_Setup file contains both the Collector agent and DC Agent installers, but the DC Agent installer is also available separately as either a .exe or .msi file named DCAgent_Setup.

To install the DC Agent

1. If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
2. Select **Next**.
3. Read and accept the license agreement. Select **Next**.

4. Optionally, you can change the installation location. Select **Next**.
5. Enter the **Collector agent IP address**.
6. If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed **Collector agent listening port** is the default. Only change this if the port is already used by another service.
7. Select **Next**.
8. Select the domains to monitor and select **Next**.
9. If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
10. Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See Configuring the FSSO Collector agent for Windows AD on page 560.
11. Select **Next**.
12. Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.
13. Select the **Working Mode** as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see DC Agent mode on page 547 and Polling mode on page 548.
14. Select **Next**.
15. Select **Yes** when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

If you want to create a redundant configuration, repeat the Collector agent installation procedure on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select **Apply**.

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. Configuring FSSO on FortiGate units on page 579 will help you accomplish these two tasks.

Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

To add the non-admin user account to the Windows 2003 security log list :

1. Go to **Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log**.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.
   A reboot is required.

To use a non-admin account with read-only permissions to install FSSO on Windows 2003:

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.
   Tools for this can be downloaded for free from http://technet.microsoft.com/en-us/sysinternals/bb897417.
2. Then create the permission string. For example:
   - `(A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)`
   - `A` means Allow,
   - `0x1` means Read, and
   - `S-1-5-21-4136056096-764329382-1249792191-1107` is the SID.
3. Then, append it to the registry key:
   `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD`
4. Repeat these steps on every domain controller in Windows 2003 AD.
   A reboot is required.

Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

Citrix TS agent installation

To install the Citrix TS agent, you must obtain the TSAgent_Setup file from the Fortinet Support web site. Perform the following installation procedure on the Citrix server.

To install the FSSO TS agent:

1. On the Citrix server, create an account with administrator privileges and a password that does not expire. See Citrix documentation for more information.

2. Log on to the account that you created in step 1.
3. Double-click the TSAgent_Setup installation file.
   The Fortinet SSO Terminal Server Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Verify that **This Host IP Address** is correct.
8. In the **FSSO Collector Agent List**, enter the IP address(es) of your Collector Agents.
9. Select **Next** and then select **Install**.
   The TS agent is installed.
10. Select **Finish**.

Novell eDirectory agent installation

To install the eDirectory agent, you must obtain the FSSO_Setup_eDirectory file from the Fortinet Support web site. Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network. You will need to provide some setup information.

To install the FSSO eDirectory agent:

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the FSSO_Setup_edirectory file to start the installation wizard.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, change the installation location. Select **Next**.
7. Enter:

eDirectory Server	
Server Address	Enter the IP address of the eDirectory server.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.

8. Select **Next**.
9. Select **Install**. When the installation completes, select **Finish**.

Updating FSSO agents on Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DCAgent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DCAgent mode, each DC Agent must be updated as well.

To update FSSO in DC Agent mode:

1. Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`.
   This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.
2. Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.
3. Go to **Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent** and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new DLL file is loaded.
4. After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

Configuring the FSSO Collector agent for Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See Configuring FortiGate group filters on page 567.

On each server with a Collector agent, you will be

- Configuring Windows AD server user groups
- Configuring Collector agent settings, including the domain controllers to be monitored
- Selecting Domain Controllers and working mode for monitoring
- Configuring Directory Access settings
- Configuring the Ignore User List
- Configuring FortiGate group filters for each FortiGate unit
- Configuring FSSO ports
- Configuring alternate user IP address tracking
- Viewing FSSO component status

Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

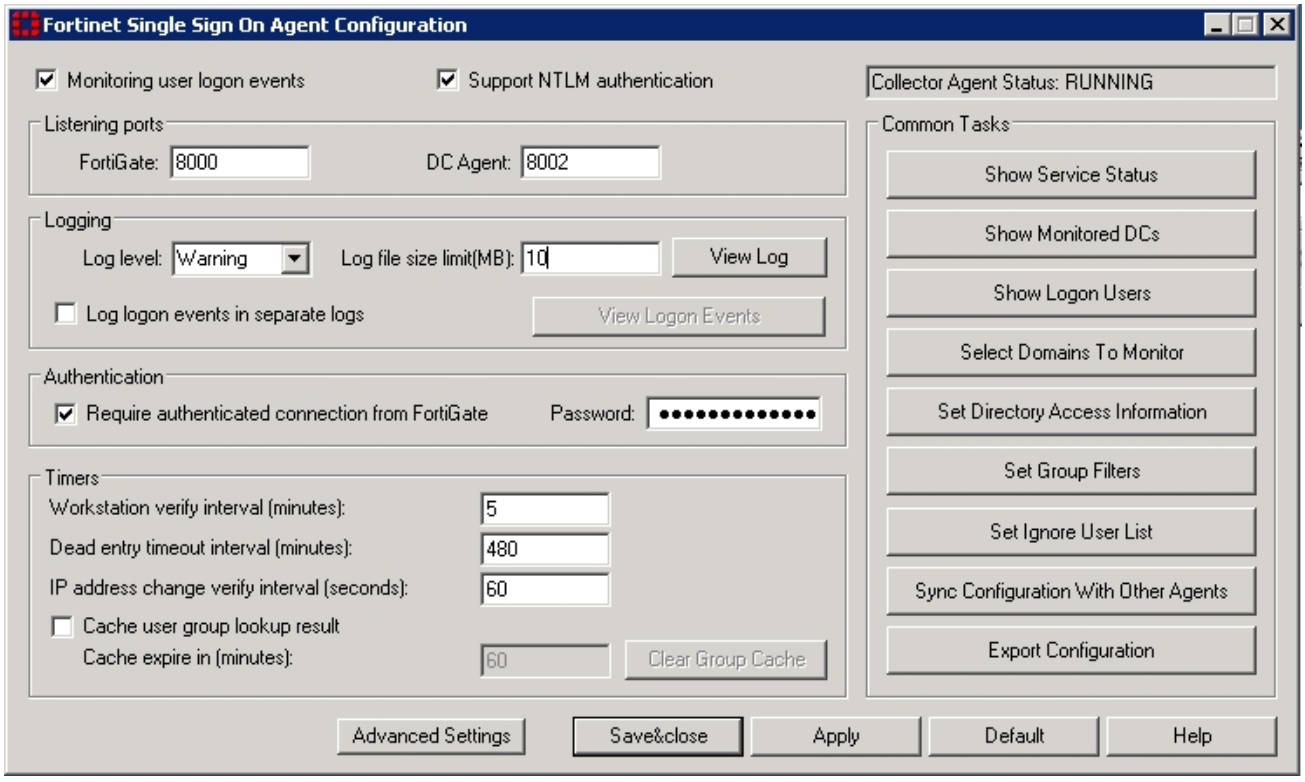
The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

Configuring Collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.



To configure the Collector agent:

1. From the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**.
2. Enter the following information.

Monitoring user logon events	By default, this is enabled to automatically authenticate users as they log on to the Windows domain. Disable the Monitor feature only if you have a large network where this feature will slow responses too much.
Support NTLM authentication	By default, this is enabled to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed. Disable NTLM authentication only if your network does not support NTLM authentication for security or other reasons.
Collector Agent Status	Shows RUNNING when Collector agent is active.

Listening ports		You can change FSSO Collector Agent related port numbers if necessary.
	FortiGate	TCP port for FortiGate units. Default 8000.
	DC Agent	UDP port for DC Agents. Default 8002.
Logging		
	Log level	Select the minimum severity level of logged messages.
	Log file size limit (MB)	Enter the maximum size for the log file in MB. Default is 10.
	View Log	View all Fortinet Single Sign On agent logs.
	Log logon events in separate logs	Record user login-related information separately from other logs. The information in this log includes: • data received from DC agents • user logon/logoff information • workstation IP change information • data sent to FortiGate units
	View Logon Events	If **Log logon events in separate logs** is enabled, you can view user login-related information.
Authentication		
	Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
	Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “fortinetcanada”. It is highly recommended to modify this password.
Timers		
	Workstation verify interval (minutes)	Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic. **Note:** This verification process creates security log entries on the client computer. If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See Configuring FSSO ports on page 568.

	Dead entry timeout interval	Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours). Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day. You can also prevent dead entry checking by setting the interval to 0.
	IP address change verify interval	Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses. Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses. This does not apply to users authenticated through NTLM.
Cache user group lookup result		Enable caching. Caching can reduce group lookups and increase performance.
	Cache expire in (minutes)	Fortinet Single Sign On Agent caches group information for logged-in users. Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires. A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.
	Clear Group Cache	Clear group information of logged-in users. This affects all logged-in users, and may force them to re-logon.

3. You can select **Save&Close** now or leave the agent configuration window open to complete additional configuration in the following sections.

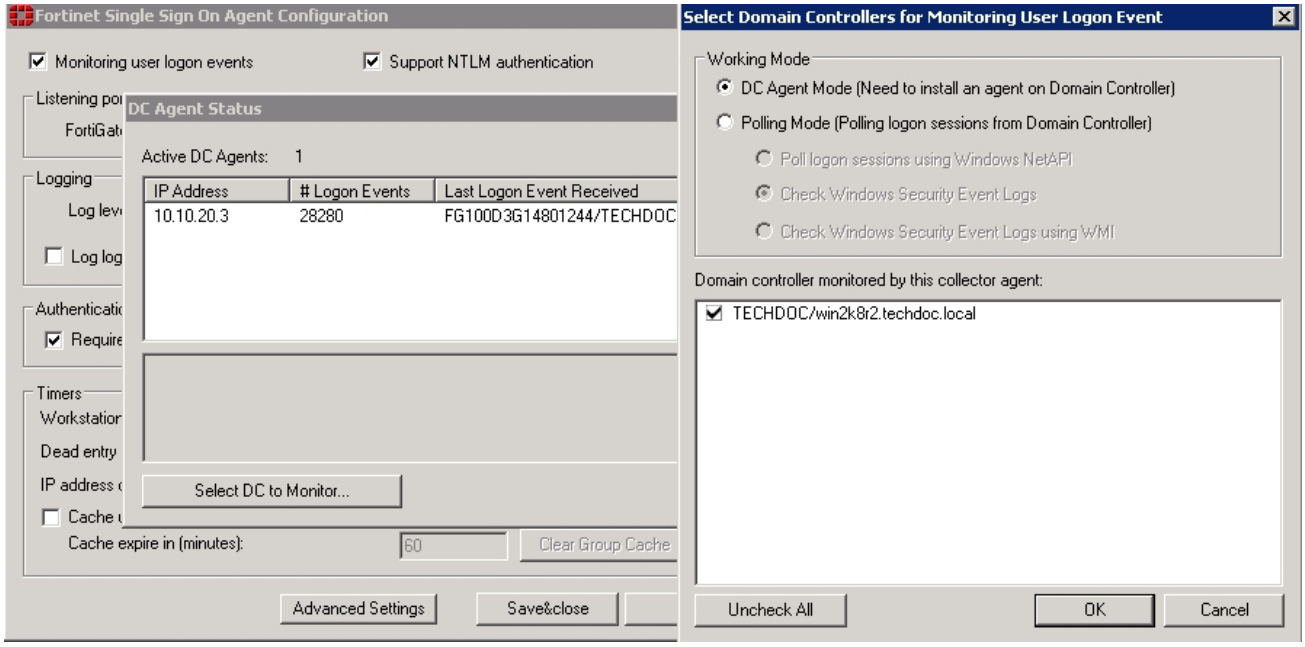
To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select **About Fortinet Single Sign On Agent configuration.**

Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1. From the Start menu select **Programs > Fortinet Fortinet Single Sign-On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
3. Select **Select DC to Monitor**.



4. Choose the **Working Mode:**
   - **DC Agent mode** — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
   - **Polling mode** — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.
5. You also need to choose the method used to retrieve logon information:
   - Poll logon sessions using Windows NetAPI
   - Check Windows Security Event Logs
   - Check Windows Security Event Logs using WMI

   For more information about these options, see Polling mode on page 548.
6. Select **OK**.
7. Select **Close**.
8. Select **Save & Close**.

Configuring Directory Access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- Standard — the FSSO Collector Agent receives group information from the Collector agent in the **domain\user** format. This option is available on FortiOS 3.0 and later.
- Advanced — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This is option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

To configure Directory Access settings:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Directory Access Information**.
   The **Set Directory Access Information** dialog box opens.
3. From the **AD access mode** list, select either **Standard** or **Advanced**.
4. If you selected Advanced AD access mode, select **Advanced Setting** and configure the following settings and then select **OK**:

AD server address	Enter the address of your network's global catalog server.
AD server port	The default AD server port is 3268. This must match your server port.
BaseDN	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default-See following example.
Username	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
Password	

BaseDN example

An example DN for Training Fortinet Canada is `ou=training, ou=canada, dc=fortinet, dc=com`. If you set the **BaseDN** to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

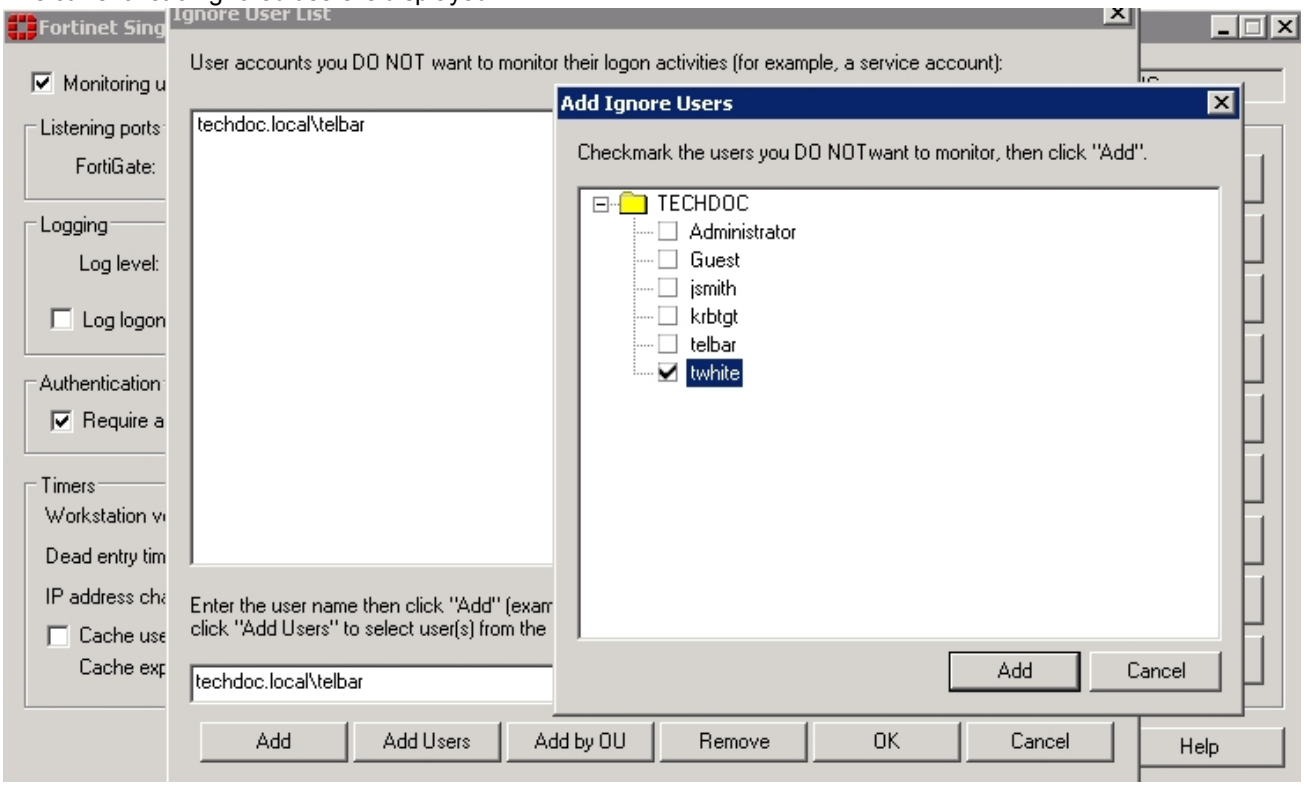
However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

Configuring the Ignore User List

The Ignore User List excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

To configure the Ignore User List:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Ignore User List**.
   The current list of ignored users is displayed:



3. Do any of the following:
   - To remove a user from the list, select the the username and then select **Remove**. The user's login is no longer ignored.
   - To add users to be ignored,
     - enter the username in the format **domain\username** and select **Add** or
     - select **Add Users**, an **Add Ignore Users** window is displayed, checkmark the users you do not want to monitor, then select **Add** or
     - select **Add by OU**, an **Add Ignore Users by OU** window is displayed, select an OU from the directory tree, then select **Add**. All users under the selected OU will be added to the ignore user list.
4. Select **OK**.

Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

To configure a FortiGate group filter:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Group Filters**.
   The FortiGate Filter List opens. It has the following columns:

FortiGate SN	The serial number of the FortiGate unit to which this filter applies.
Description	An optional description of the role of this FortiGate unit.
Monitored Groups	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
Add	Create a new filter.
Edit	Modify the filter selected in the list.
Remove	Remove the filter selected in the list.
OK	Save the filter list and exit.
Cancel	Cancel changes and exit.

3. Select **Add** to create a new filter. If you want to modify an existing filter, select it in the list and then select **Edit**.
4. Enter the following information and then select **OK**.

Default filter	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
FortiGate Serial Number	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
Description	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
Monitor the following groups	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.
Add	In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead. The format of the entry depends on the AD access mode (see Configuring Directory Access settings on page 565): Standard: Domain\Group Advanced: cn=group, ou=corp, dc=domain
Advanced	Select **Advanced**, select the user groups from the list, and then select **Add**.
Remove	Remove the user groups selected in the monitor list.

Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. There ports listed in this section assume the default FSSO ports are used.

TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent **workstation verify interval** to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

Configuring ports on the Collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002.

For more information about setting these ports, see Configuring FSSO Advanced Settings on page 574.

Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

To configure alternate user IP address tracking:

1. On the computer where the Collector agent is installed, go to **Start > Run**.
2. Enter `regedit` or `regedt32` and select **OK**.
   The Registry Editor opens.
3. Find the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent.
4. Set the supportFSAEauth value (dword) to 00000001.
   If needed, create this new dword.
5. Close the Registry Editor.
6. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
7. Select **Apply**.
   The Fortinet Single Sign On Agent service restarts with the updated registry settings.

Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

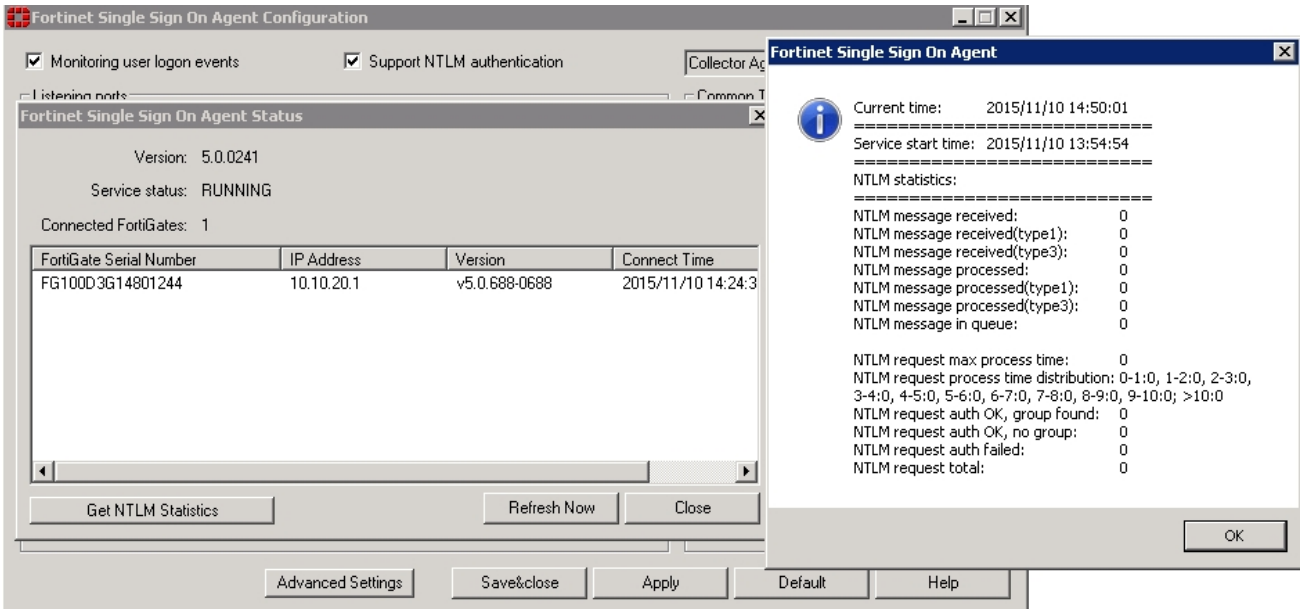
Viewing Collector agent status

Use the **Show Service Status** to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and connect time

To view Collector agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Service Status**.
   The Fortinet Single Sign On Collector agent Status window opens.
3. Optionally select **Get NTLM statistics** in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.



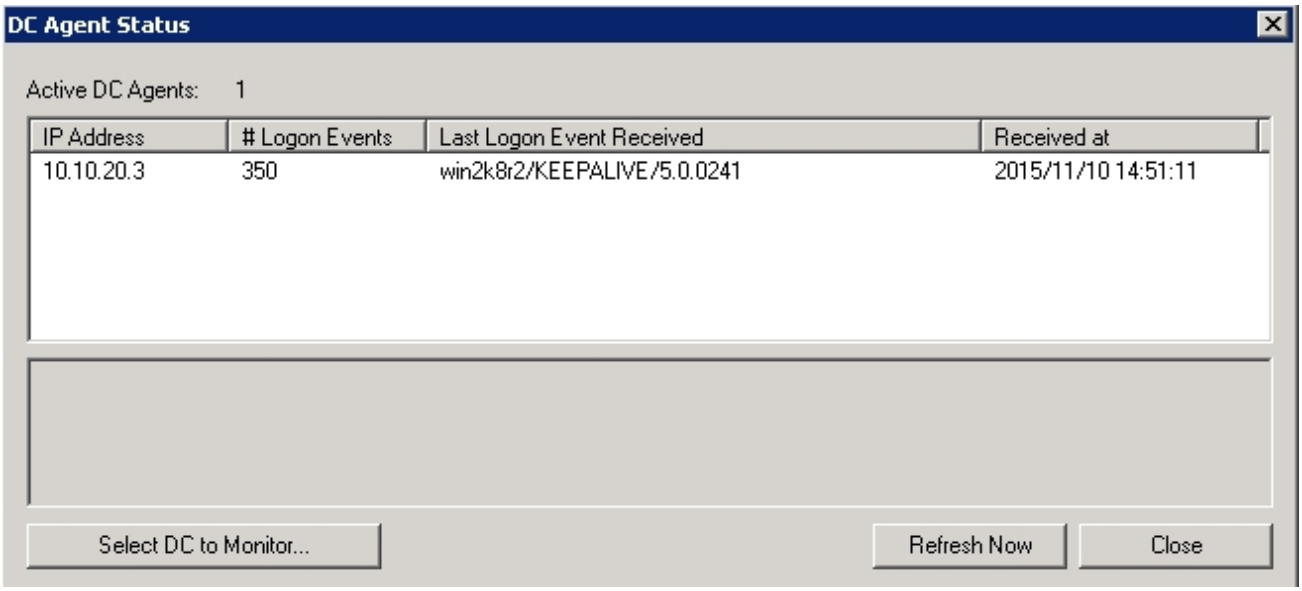
Viewing DC agent status

Use the **Show Monitored DCs** to view the status of DC agents.

To view domain controller agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
   For each DC Agent, the following information is displayed:
   - IP address
   - number of logon events received
   - the last logon event
   - when last logon was received

To change which DC agents are monitored or change the working mode for logon event monitoring, select **Select DC to Monitor**



Configuring the FSSO TS agent for Citrix

The FSSO TS agent works with the same FSSO Collector agent that is used for integration with Windows Active Directory. Install the Collector agent first. Follow the Collector agent installation procedure in Collector agent installation on page 554.

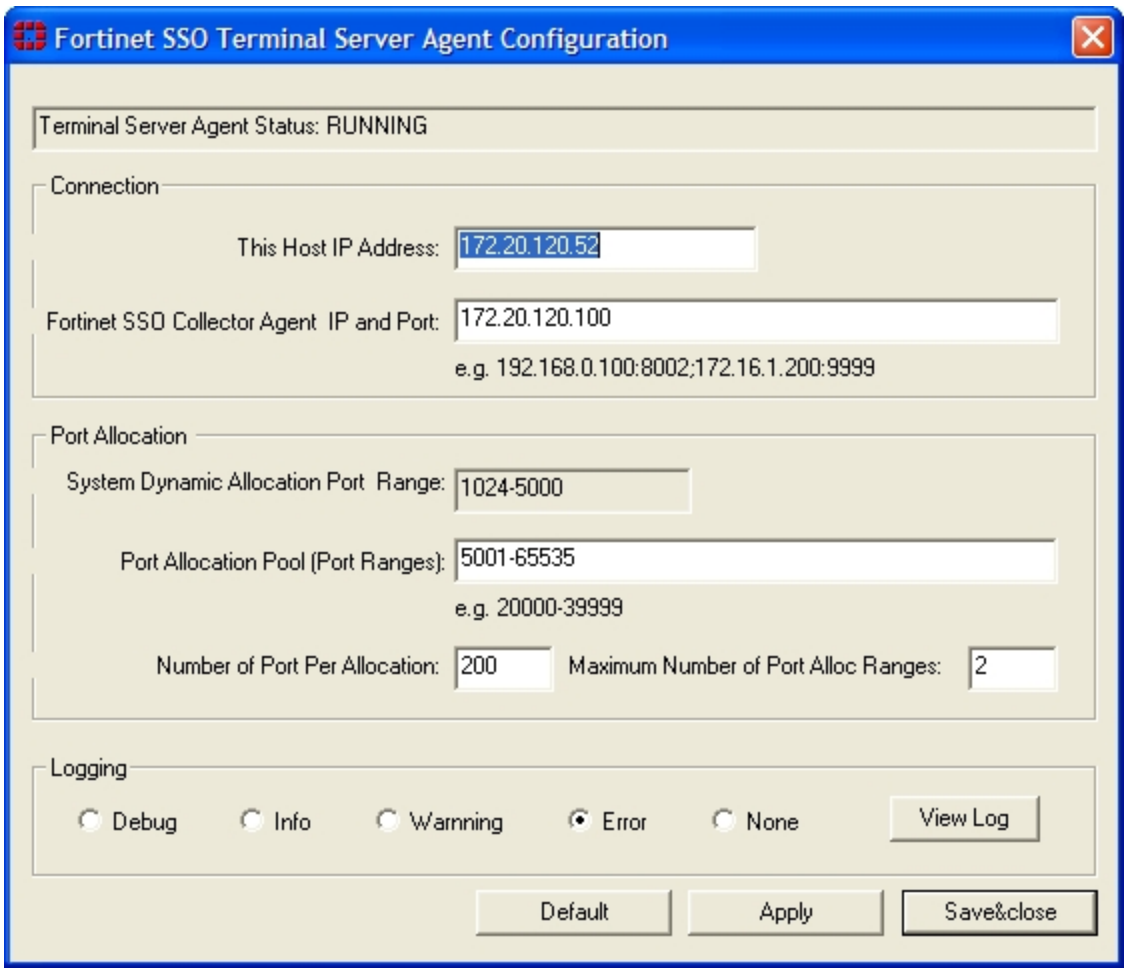
Configuration steps include:

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate Single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

To change the TS agent configuration, select from the Start menu **Programs > Fortinet > Fortinet Single Sign-On Agent > TSAgent Config**. In addition to the host and Collector agent IP addresses that you set during installation, you can adjust port allocations for Citrix users. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

Fortinet SSO Collector Agent IP and Port needs to point to the current configured listening port on the collector which is port 8002 by default. Though it may be configured to a custom port.

Configuring the TS agent



Configuring FSSO with Novell networks

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- Configuring the eDirectory agent
- Adding an eDirectory server
- Configuring a group filter

Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

To configure the eDirectory agent:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. The eDirectory Agent Configuration Utility dialog opens. Enter the following information and select **OK**.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
Password	Enter the password.
Listening port	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
Refresh interval	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.

FortiGate Connection Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “FortinetCanada”.
User logon Info Search Method	Select how the eDirectory agent accesses user logon information: **LDAP** or **Native** (Novell API). LDAP is the default. If you select **Native**, you must also have the Novell Client installed on the PC.

Logging	
Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View the current log file.
Dump Session	List the currently logged-on users in the log file. This can be useful for troubleshooting.
Log level	Select **Debug, Info**, **Warning** or **Error** as the minimum severity level of message to log or select **None** to disable logging.

eDirectory Server List	
Add	Add an eDirectory server. See Adding an eDirectory server on page 574.
Delete	Delete the selected eDirectory server.
Edit	Modify the settings for the selected server.
Set Group Filters...	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

To add an eDirectory server:

1. In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, Configuring the eDirectory agent), select **Add**.
2. The eDirectory Setup dialog box opens. Enter the following information and select OK:

eDirectory Server Address	Enter the IP address of the eDirectory server.
Port	If the eDirectory server does not use the default port 389, clear the **Default** check box and enter the port number.
Use default credential	Select to use the credentials specified in the eDirectory Configuration Utility. See Configuring the eDirectory agent on page 572. Otherwise, leave the check box clear and enter a username and Password below.
User name	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor or configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

To configure the group filter:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. Select **Set Group Filters**.
3. Do one of the following:
   - Enter group names, then select **Add**.
   - Select **Advanced**, select groups, and then select **Add**.
4. Select **OK**.

Configuring FSSO Advanced Settings

Depending on your network topologies and requirement, you may need to configure advanced settings in the FSSO Colloctor agent.To do so, from the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**, then from the **Common Tasks** section, select **Advanced Settings**.

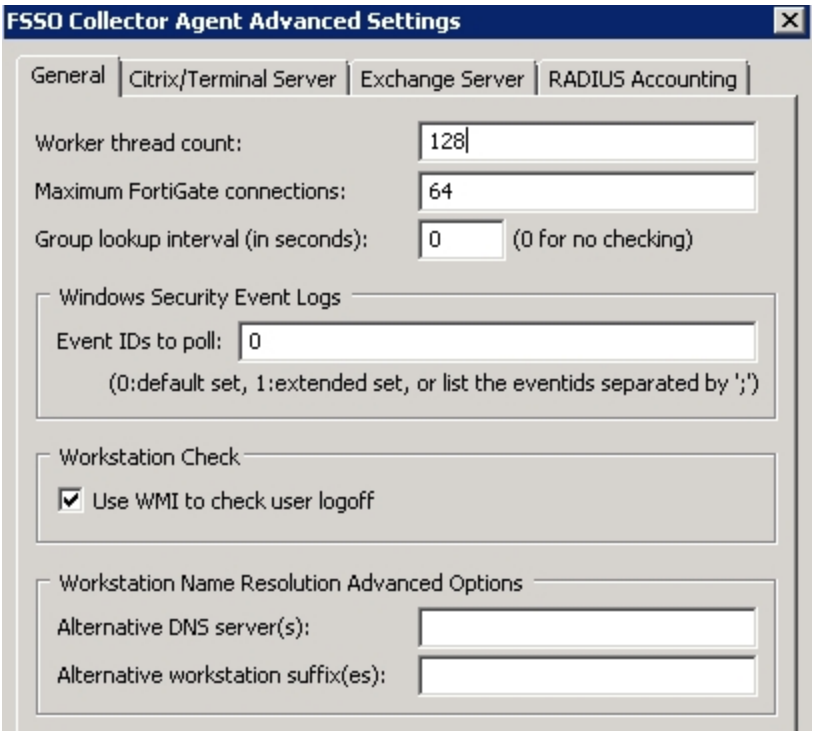
This section include :

- General Settings
- Citrix/Terminal Server
- Exchange Server
- RADIUS Accounting

General Settings

In the General tab, enter the following information and select **OK**.

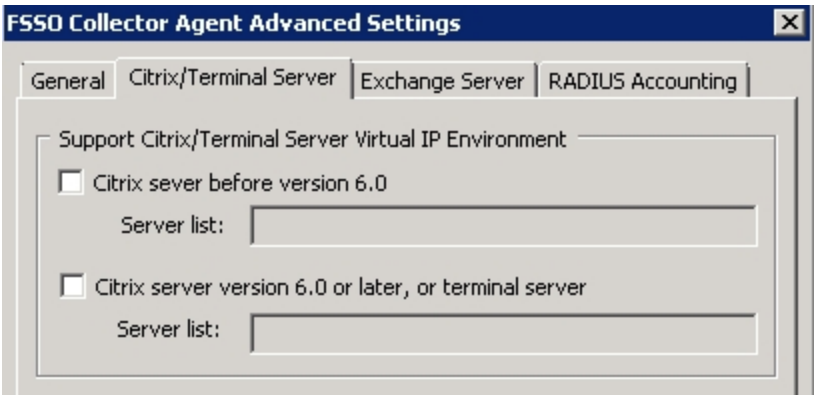
Worker thread count	Number of threads started in the CA process. Default is128 on CA version 5.0.0241.
Maximum FortiGate connections	Number of FortiGates can be connected to the CA. Default is 64.
Group look-up interval	The interval in seconds to lookup users/groups. If an AD group membership of currently logged on user, CA can detect this and update information on the FortiGate. Enter 0 for no checking.
Windows security Event logs	Choose the event logs to poll.
Event IDs to poll	0:Default set, it includes Kerberos authentication event logs : 672 for Windows server 2003, 4768 for Windows server 2008 and 2012 and NTLM authentication event logs : 680 for Windows server 2003, 4776 for Windows server 2008 and 2012. 1: Extended set, it includes Kerberos service ticket event logs : 673 for Windows server 2003, 4769 for Windows server 2008 and 2012. Service tickets are obtained whenever a user or computer accesses a server on the network. List the event ids separated by ";".
Workstation Check	Optianally enable **Use WMI to check user logoff** for the collector agent to query whether users is still logged on.
Workstation Name Resolution Advance Options	
Alternative DNS server (s)	Collector Agent uses the DNS server configured on the machine it is running on by default. If CA should use another DNS server then one or more alternative DNS server can be configured here.
Alternative workstation suffix(es)	If only host name is available CA uses the default domain suffix to build a FQDN for DNS queries. In case CA should use a different suffix, it can be configured as well.



Citrix/Terminal Server

In the Citrix/Terminal Server tab, enter the following information and select **OK**.

Support Citrix/Terminal Server Virtual IP Environment	When Citrix server are configured with VIP, CA can get user logon events from theses server. Citrix changed their interface and data format so version of Citrix server is important.
Citrix server before version 6.0	Enable this option if you Citrix server version is before 6.0.
Server list	Enter the list of servers separated by colon.
Citrix server version 6.0 or later, or Terminal Server	Enable this option if you Citrix server version is 6.0 or later.
Server list	Enter the list of servers separated by colon.

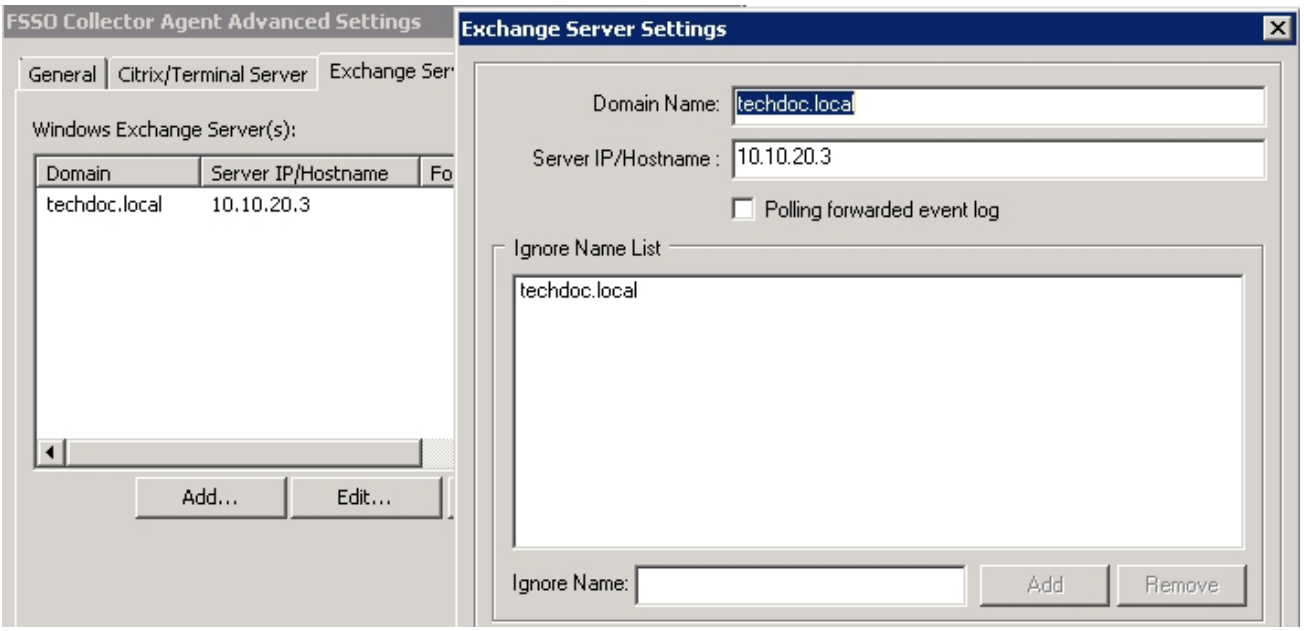


Exchange Server

FSSO supports monitoring Microsoft Exchange Server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings** > **Exchange Server**.

Select **Add** and enter the following information and select **OK**.

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the **Ignore Name** field and select **Add**.



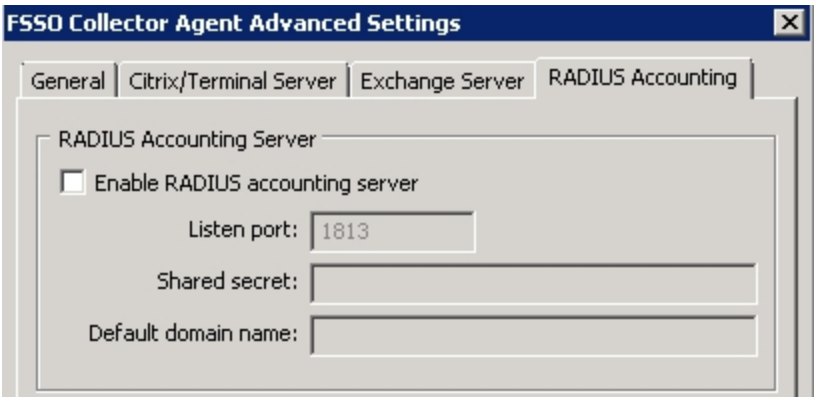
RADIUS Accounting

A RADIUS server must be configured in your network to send accounting messages to the Collector Agent which can be configured to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the Collector Agent. User group names do not need to be added for all users, only to the accounts of users who will use RADIUS Accounting feature on the Collector Agent.
- Configure your accounting system to send RADIUS Start records to the Collector Agent.

The Collocter Agent should be configured to listen for RADIUS accounting messages as following.

RADIUS Accounting Server	
Enable RADIUS Accounting Server	Enable this option to allow the CA to gather information about authenticated users via a RADIUS server and send these information to the FortiGate unit for monitoring.
Listen port	The port on which CA listens for RADIUS accounting messages. Default RADIUS accounting is 1813, but if RADIUS server sends accounting messages on different port, value can be configured here.
Shared secret	Common secret between CA and RADIUS server.
Default domain name	This should be the AD domain for which this CA is configured. In this case user name in RADIUS accounting message can be in simple format like `user1`. If this value is empty, then user name in RADIUS accounting message must be in one of these formats `user1@domain`, `Domain\user1` or `domain/user1`. CA will use user name and domain to query group membership of user. Client IP address (Framed IP) should also be in RADIUS accounting message, so that CA can forward user name, IP address and groups to the FortiGate.



Configuring FSSO on FortiGate units

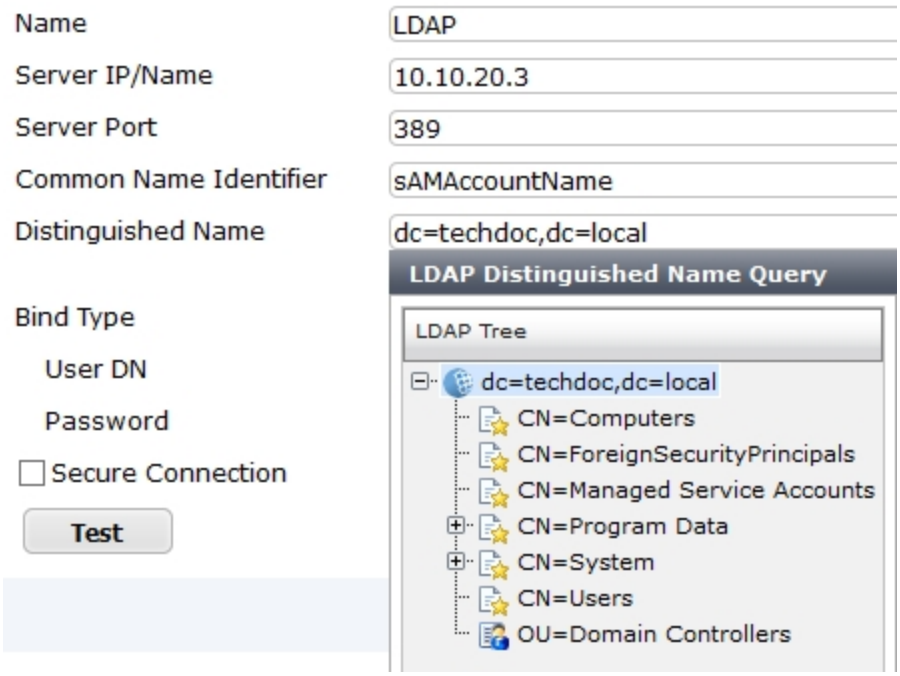
To configure your FortiGate unit to operate with agent-based FSSO, you

- Configure any access to LDAP servers that might be necessary. Skip this step if you are using FSSO Standard mode. See Configuring LDAP server access on page 579.
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See Specifying your Collector agents or Novell eDirectory agents on page 581.
- Add Active Directory user groups to FortiGate user groups. See Creating Fortinet Single Sign-On (FSSO) user groups on page 582.
- Create security policies for FSSO-authenticated groups. See Creating security policies on page 583.
- Optionally, specify a guest security policy to allow guest access. See Enabling guest access through FSSO security policies on page 584.

Configuring LDAP server access

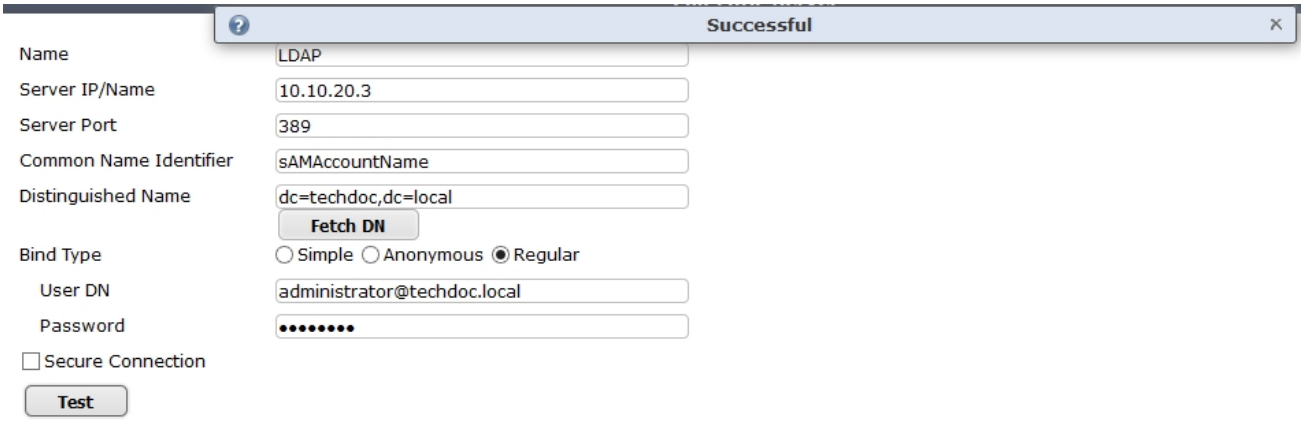
LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to Specifying your Collector agents or Novell eDirectory agents on page 581.

1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**.The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is dc=techdoc,dc=local
5. Select **Fetch DN**, this will fetch the Windows AD directory.



6. Set **Bind Type** to **Regular.**
7. In the **User DN** field, enter the administrative account name that you created for FSSO.
   For example, if the account is administrator, enter “administrator@techdoc.local”.
8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
   - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
   - In the **Certificate** field, select the appropriate certificate for authentication.

   Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.



To configure LDAP for FSSO - CLI example:

```
config user ldap
   edit LDAP
      set server 10.10.20.3
```

```
        set cnid sAMAccountName
        set dn dc=techdoc,dc=local
        set type regular
        set username administrator@techdoc.local
        set password <your_password>
    next
end
```

Specifying your Collector agents or Novell eDirectory agents

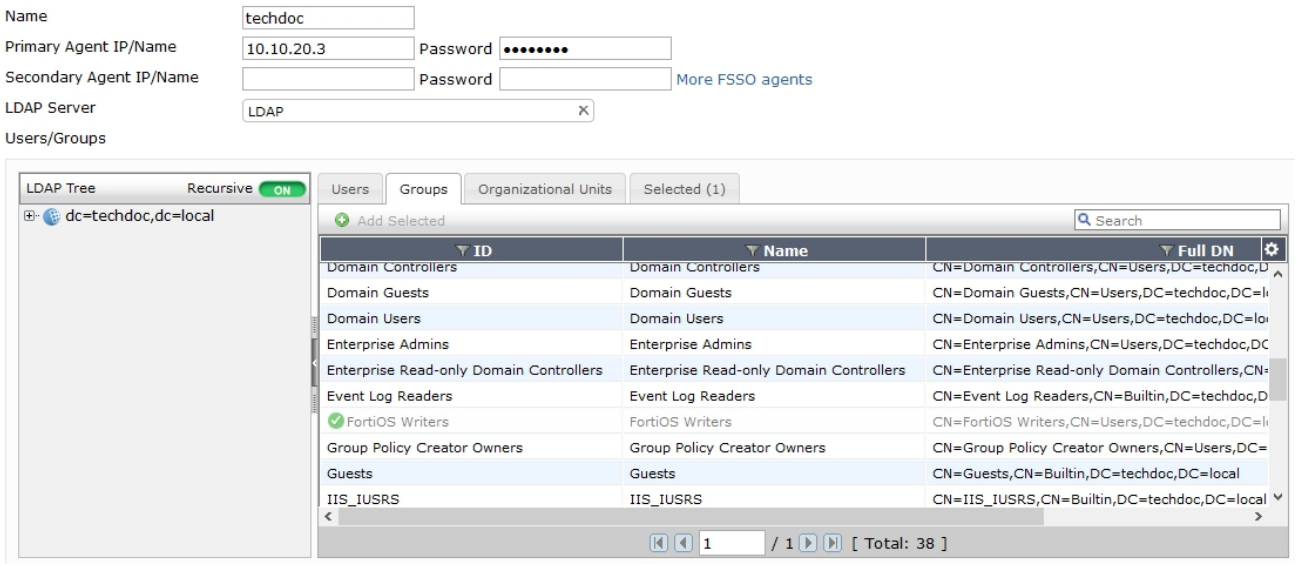
You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

To specify Collector agents - web-based manager:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the following information for each of up to five collector agents and select **OK**:

Agent IP/Name	Enter the IP address or the name of the server where this agent is installed. Maximum name length is 63 characters. If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the `config user fsso` command. See Configuring Collector agent settings on page 561.
Password	Enter the password for the Collector agent or eDirectory agent. For the Collector agent, this is required only if you configured the agent to require authenticated access.

5. For Novell eDirectory or Windows AD with Collector agent in Advanced AD access mode select the **LDAP Server** you configured previously. See Configuring LDAP server access on page 579.
6. In **Users/Groups**, select the **Users** or **Groups** or **Organizational Units** tab and then select the users or groups or OU that you want to monitor.
7. Select **OK**.



To specify the FSSO Collector agent - CLI:

In this example, the SSO server name is techdoc and the LDAP server is LDAP.

```
config user fsso
   edit techdoc
      set ldap-server LDAP
      set password <your_password>
      set server 10.10.20.3
      set port 8000
   end
```

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User > User Groups**.
2. Select **Create New**.
   The New User Group dialog box opens.
3. In the **Name** box, enter a name for the group, FSSO_Internet_users for example.
4. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
5. In **Members**, select the required **FSSO** groups.
6. Select **OK**.

To create the FSSO_Internet-users user group - CLI :

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
```

```
end
```

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > Policy > IP4** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	`fsso_group`
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select **Security Events**.

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port1
```

```
    set dstintf port2
    set srcaddr company_network
    set dstaddr all
    set action accept
    set groups fsso_group
    set schedule always
    set service HTTP HTTPS FTP TELNET
    set nat enable
end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged too was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services. Creating security policies on page 583

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO-related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging". For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

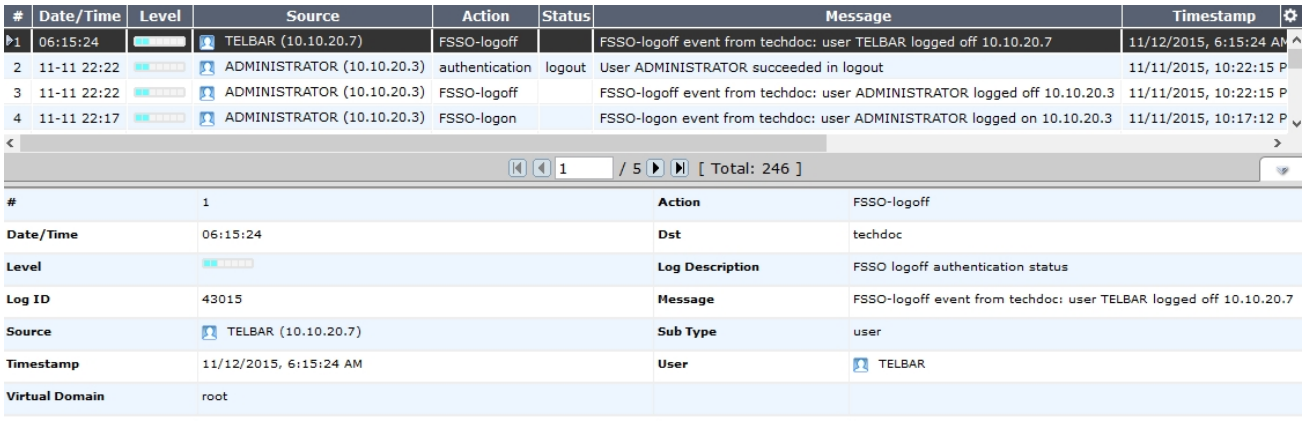
To enable event logging:

1. Go to **Log&Report > Log Config > Log Settings**.
2. In **Event Logging**, select:

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Optionally you can enable any or all of the other logging event options.
4. Select **Apply**.

Authentication log messages



List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see Troubleshooting FSSO on page 587.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:
   ```
   diagnose debug authd fsso list
   ```
4. Check the output. If FSSO is functioning properly you will see something similar to the following:
   ```
   ----FSSO logons----
   IP: 10.10.20.3 User: ADMINISTRATOR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
       Workstation: WIN2K8R2.TECHDOC.LOCAL MemberOf: FortiOS_Writers
   IP: 10.10.20.7 User: TELBAR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
       Workstation: TELBAR-PC7.TECHDOC.LOCAL
   Total number of logons listed: 2, filtered: 0
   ----end of FSSO logons----
   ```
   The exact information will vary based on your installation.
5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:
   ```
   FGT# diagnose debug enable
   FGT# diagnose debug authd fsso server-status
   ```

```
FGT# Server Name Connection Status Version
     ----------- ----------------- -------
     techdoc       connected FSSO 5.0.0241
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) cannot access the network
- Guest users do not have access to network
- Can't find the DCagent service
- User logon events not received by FSSO Collector agent
- Mac OS X users can't access external resources after waking from sleep mode

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.
  If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

Users on a particular computer (IP address) cannot access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called **SSO_Guest_Users**. Ensure that group is part of an identity-based security policy to allow traffic.

Can't find the DCagent service

The DCagent service can't be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

Solution

To verify that the DCagent is installed properly

1. Check that DCagent.dll exists in `Windows\system32` folder.
2. Check that the registry key exists: `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

User logon events not received by FSSO Collector agent

When a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

If NetAPI polling mode is enabled, consider switching to Event logs or Event Logs using WMI polling as it provides better accuracy.

Mac OS X users can't access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSSO. This results in the FortiGate blocking access to the user because they cannot be authenticated.

Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

SSO using RADIUS accounting records

A FortiGate unit can authenticate users transparently who have already authenticated on an external RADIUS server. Based on the user group to which the user belongs, the security policy applies the appropriate UTM profiles. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server emits. These records include the user's IP address and user group.

After the initial set-up, changes to the user database, including changes to user group memberships, are made on the external RADIUS server, not on the FortiGate unit.

This section describes:

- User's view of RADIUS SSO authentication
- Configuration Overview
- Configuring the RADIUS server
- Creating the FortiGate RADIUS SSO agent
- Defining local user groups for RADIUS SSO
- Creating security policies
- Example: webfiltering for student and teacher accounts

User's view of RADIUS SSO authentication

For the user, RADIUS SSO authentication is simple:

- The user connects to the RADIUS server and authenticates.
- The user attempts to connect to a network resource that is reached through a FortiGate unit. Authentication is required for access, but the user connects to the destination without being asked for logon credentials because the FortiGate unit knows that the user is already authenticated. FortiOS applies UTM features appropriate to the user groups that the user belongs to.

Configuration Overview

The general steps to implement RADIUS Single Sign-On are:

1. If necessary, configure your RADIUS server. The user database needs to include user group information and the server needs to send accounting messages.
2. Create the FortiGate RADIUS SSO agent.
3. Define local user groups that map to RADIUS groups.
4. Create a security policy which specifies the user groups that are permitted access.

Configuring the RADIUS server

You can configure FortiGate RSSO to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. User group names do not need to be added for all

users, only to the accounts of users who will use RSSO feature on the FortiGate unit.

- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiGate network interface. If your FortiGate unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

Creating the FortiGate RADIUS SSO agent

Once you define a RADIUS SSO (RSSO) agent, the FortiGate unit will accept user logon information from any RADIUS server that has the same shared secret. You can create only one RSSO agent in each VDOM.

Before you create the RSSO agent, you need to allow RADIUS accounting information on the interface that connects to the RADIUS server.

To enable RADIUS access on the interface - web-based manager:

1. Go to **System > Network > Interfaces** and edit the interface to which the RADIUS server connected.
2. Select **Listen for RADIUS Accounting Messages**.
3. Select **OK**.

To enable RADIUS access on the interface - CLI:

In this example, the port2 interface is used.

```
config system interface
   edit port2
      set allowaccess radius-acct
   end
```

To create a RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

To create a RADIUS SSO agent - CLI

```
config user radius
   edit RSSO_Agent
      set rsso enable
      set rsso-validate-request-secret enable
      set rsso-secret <your secret>
      set rsso-radius-response enable
   end
```

Selecting which RADIUS attributes are used for RSSO

For RADIUS SSO to work, FortiOS needs to know the user's endpoint identifier (usually IP address) and RADIUS user group. There are default RADIUS attributes where FortiOS expects this information, but you can change these attributes in the `config user radius` CLI command.

RSSO information and RADIUS attribute defaults

RSSO Information	RADIUS Attribute	CLI field
Endpoint identifier	Calling-Station-ID	`rsso-endpoint-attribute`
Endpoint block attribute	Called-Station-ID	`rsso-endpoint-block-attribute`
User group	Class	`sso-attribute`

The Endpoint block attribute can be used to block or allow a user. If the attribute value is set to the name of an attribute that indicates whether to block or allow, FortiOS blocks or allows respectively all traffic from that user's IP address. The RSSO fields are visible only when `rsso` is set to `enable`.

Configuring logging for RSSO

In the `config user radius` CLI command, you can set the following flags in the `rsso-log-flags` field to determine which types of RSSO-related events are logged:

- `protocol-error` — A RADIUS protocol error occurred.
- `profile-missing` — FortiOS cannot find a user group name in a RADIUS start message that matches the name of an RSSO user group in FortiOS.
- `accounting-stop-missed` — a user context entry expired without FortiOS receiving a RADIUS Stop message.
- `accounting-event` — FortiOS did not find the expected information in a RADIUS record.
- `endpoint-block` — FortiOS blocked a user because the RADIUS record's endpoint block attribute had the value "Block".
- `radiusd-other` — Other events, described in the log message.

Defining local user groups for RADIUS SSO

You cannot use RADIUS user groups directly in security policies. Instead, you create locally-defined user groups on the FortiGate unit and associate each of them with a RADIUS user group.

To define local user groups for RADIUS SSO:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

To define local user groups for RADIUS SSO:

This example creates an RSSO user group called RSSO-1 that is associated with RADIUS user group "student".

```
config user group
   edit RSSO-1
      set group-type rsso
      set sso-attribute-value student
```

```
end
```

Creating security policies

RADIUS SSO uses regular identity-based security policies. The RSSO user group you specify determines which users are permitted to use the policy. You can create multiple policies if user groups can have different UTM features enabled, different permitted services, schedules, and so on.

To create a security policy for RSSO - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Enter the following information.

Incoming Interface	as needed
Source Address	as needed
Source User(s)	Select the user groups you created for RSSO. See Defining local user groups for RADIUS SSO on page 591.
Outgoing Interface	as needed
Destination Address	all
Schedule	as needed
Service	as needed
Action	ACCEPT
Enable NAT	Selected
Security Profiles	Select security profiles appropriate for the user group.

4. Select **OK**.

   To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
5. Select **OK**.

To create a security policy for RSSO - CLI:

In this example, an internal network to Internet policy enables web access for members of a student group and activates the appropriate UTM profiles.

```
config firewall policy
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr "all"
      set action accept
      set rsso enable
```

```
    set groups "RSSO-student"
    set schedule always
    set service HTTP HTTPS
    set nat enable
    set utm-status enable
    set av-profile students
    set webfilter-profile students
    set spamfilter-profile students
    set dlp-sensor default
    set ips-sensor default
    set application-list students
    set profile-protocol-options "default"
end
```

Example: webfiltering for student and teacher accounts

The following example uses RADIUS SSO to apply web filtering to students, but not to teachers. Assume that the RADIUS server is already configured to send RADIUS Start and Stop records to the FortiGate unit. There are two RADIUS user groups, **students** and **teachers**, recorded in the default attribute **Class**. The workstations are connected to port1, port2 connects to the RADIUS server, and port3 connects to the Internet.

Configure the student web filter profile:

1. Go to **Security Profiles > Web Filter** and select **Create New** (the "+" button).
2. Enter the following and select **OK**.

Name	student
Inspection Mode	Proxy
FortiGuard Categories	Enable. Right-click the **Potentially Liable** category and select **Block**. Repeat for **Adult/Mature Content** and **Security Risk**.

Create the RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

Define local user groups associated with the RADIUS SSO user groups:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following and select **OK**.

Name	RSSO-students
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	students

3. Select **Create New**, enter the following and select **OK**.

Name	RSSO-teachers
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	teachers

Create a security policy for students:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter

Incoming Interface	port1
Source Address	all
Source User(s)	RSSO-students
Source Device Type	All
Outgoing Interface	port3
Destination Address	all
Schedule	always
Service	HTTP, HTTPS
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus, Web Filter, IPS. In Web Filter, select the **student** profile.

3. Select **OK**.

Create a security policy for teachers:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter

Incoming Interface	port2
Source Address	all
Source User(s)	RSSO-teachers
Source Device Type	All
Outgoing Interface	port3

Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus and IPS.

3. Select **OK**.

Monitoring authenticated users

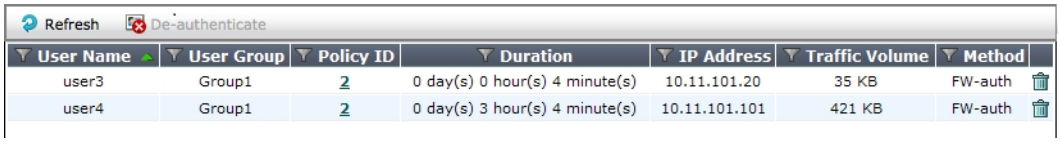
This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

The following topics are included in this section:

- Monitoring firewall users
- Monitoring SSL VPN users
- Monitoring IPsec VPN users
- Monitoring users Quarantine

Monitoring firewall users

To monitor firewall users, go to **User & Device > Monitor > Firewall.**



You can de-authenticate a user by selecting the Delete icon for that entry.

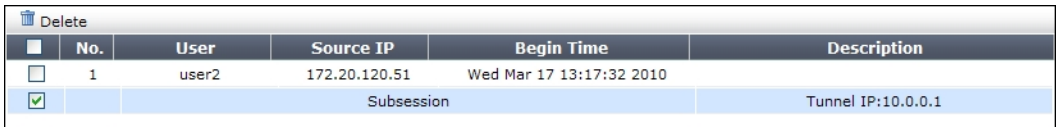
You can filter the list of displayed users by selecting the funnel icon for one of the column titles or selecting **Filter Settings**.

Optionally, you can de-authenticate multiple users by selecting them and then selecting **De-authenticate**.

Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to **VPN > Monitor > SSL-VPN Monitor**. To disconnect a user, select the user and then select the **Delete** icon.



The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The **Description** column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the FortiOS Handbook SSL VPN guide.

To monitor SSL VPN users - CLI:

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
 Index   User   Auth Type   Timeout         From      HTTPS in/out
 0       user1  1           256       172.20.120.51   0/0

SSL-VPN sessions:
 Index   User   Source IP        Tunnel/Dest IP
 0       user2  172.20.120.51    10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

To disconnect all SSL VPN users in this VDOM

```
execute vpn ssl del-all
```

Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to **VPN > Monitor > IPsec Monitor**. user names are available only for users who authenticate with XAuth.

You can close a tunnel by selecting the tunnel and right click to select **Bring Down**.

For more information, see the FortiOS Handbook IPsec VPN guide.

Monitoring users Quarantine

The User Quarantine list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by Data Leak Prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the User Quarantine list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the User Quarantine list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure **Quarantine** in an IPS Filter.
- **Users or IP addresses that are quarantined by Data Leak Prevention** - In a DLP sensor select **Quarantine IP Address** as the action to take.

For more information, see FortiOS Handbook Security Profiles guide.

Users are viewed from **User & Device > Monitor > User Quarantine.**

Delete	Removes the selected user or IP address from the User Quarantine list.
Remove All	Removes all users and IP addresses from the User Quarantine list.
Search	Search the list for a particular IP address.
Source	The FortiGate function that caused the user or IP address to be added to the User Quarantine list: IPS or Data Leak Prevention.
Created	The date and time the user or IP address was added to the Banned User list.
Expires	The date and time the user or IP address will be automatically removed from the User Quarantine list. If **Expires** is **Indefinite**, you must manually remove the user or host from the list.

Examples and Troubleshooting

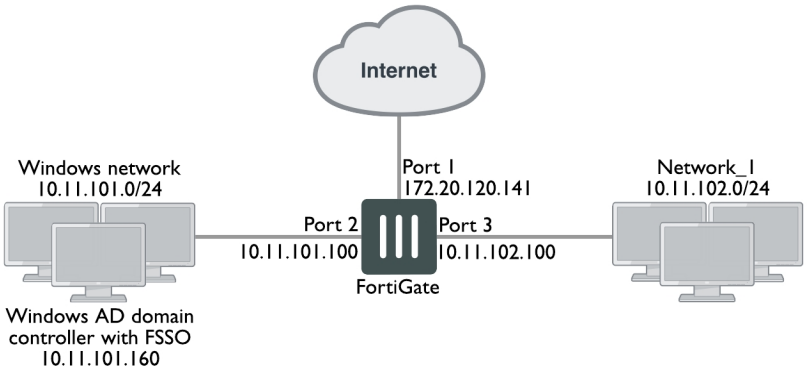
This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

- Firewall authentication example
- LDAP Dial-in using member-attribute example
- RADIUS SSO example
- Troubleshooting

Firewall authentication example

Example configuration



Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

To create a local user - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Local User
User Name	User1
Password	hardtoguess
Email Address **SMS**	(optional)
Enable	Select.

To create a local user - CLI:

```
config user local
   edit user1
      set type password
      set passwd hardtoguess
   end
```

Creating a RADIUS-authenticated user account

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

To configure the remote authentication server - web-based manager:

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**:

Name	OurRADIUSsrv
Primary Server Name/IP	10.11.101.15
Primary Server Secret	OurSecret
Authentication Scheme	Select **Use Default Authentication Scheme**.

To configure the remote authentication server - CLI:

```
config user radius
   edit OurRADIUSsrv
      set server 10.11.102.15
      set secret OurSecret
      set auth-type auto
   end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

To configure a remote user - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Remote RADIUS User
User Name	User2
RADIUS server	OurRADIUSsrv
Email Address **SMS**	(optional)
Enable	Select

To configure a remote user - CLI:

```
config user local
   edit User2
      set name User2
      set type radius
      set radius-server OurRADIUSsrv
   end
```

Creating user groups

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

Creating the FSSO user group

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

To configure LDAP for FSSO - web-based manager:

1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter the following information:

Name	ADserver
Server Name / IP	10.11.101.160
Distinguished Name	dc=office,dc=example,dc=com

Bind Type	Regular
User DN	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
Password	set_a_secure_password

3. Leave other fields at their default values.
4. Select **OK**.

To configure LDAP for FSSO - CLI"

```
config user ldap
   edit "ADserver"
      set server "10.11.101.160"
      set dn "cn=users,dc=office,dc=example,dc=com"
      set type regular
      set username "cn=administrator,cn=users,dc=office,dc=example,dc=com"
      set password set_a_secure_password
   next
end
```

To specify the collector agent for FSSO - web-based manager

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New.**
2. Enter the following information:

Type	Fortinet Single Sign-On Agent
Name	WinGroups
Primary Agent IP/Name	10.11.101.160
Password	fortinet_canada
LDAP Server	ADserver

3. Select **Apply & Refresh**.

In a few minutes, the FortiGate unit downloads the list of user groups from the server.

To specify the collector agent for FSSO - CLI:

```
config user fsso
   edit "WinGroups"
      set ldap-server "ADserver"
      set password ENC
          G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFDr0RmY3c4LaoXdsoBczA
          1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
      set server "10.11.101.160"
   end
```

To create the FSSO_Internet-users user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	FSSO_Internet_users
Type	Fortinet Single Sign-On (FSSO)
Members	Engineering, Sales

To create the FSSO_Internet-users user group - CLI:

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
   end
```

Creating the Firewall user group

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

To create the firewall user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Internet_users
Type	Firewall
Members	User1, User2

To create the firewall user group - CLI:

```
config user group
   edit Internet_users
      set group-type firewall
      set member User1 User2
   end
```

Defining policy addresses

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create the following addresses:

Address Name	Internal_net
Type	Subnet
Subnet / IP Range	10.11.102.0/24
Interface	Port 3

Address Name	Windows_net
Type	Subnet
Subnet / IP Range	10.11.101.0/24
Interface	Port 2

Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

To create a security policy for FSSO authentication - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port2
Source Address	Windows_net
Source User(s)	FSSO_Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select OK.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr Windows_net
      set dstaddr all
      set action accept
      set groups FSSO_Internet_users
      set schedule always
      set service ANY
      set nat enable
   end
```

To create a security policy for local user authentication - web-based manager

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port3
Source Address	Internal_net
Source User(s)	Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select **OK**.

To create a security policy for local user authentication - CLI

```
config firewall policy
   edit 0
      set srcintf port3
      set dstintf port1
      set srcaddr internal_net
      set dstaddr all
      set action accept
      set schedule always
      set groups Internet_users
      set service ANY
      set nat enable
   end
```

LDAP Dial-in using member-attribute example

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to set up a VPN connection simply based on an attribute that is set to TRUE, instead of based on their user group. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
   edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=fortilabanz,DC=com,DC=au"
      set type regular
      set username "fortigate@sample.com"
      set password ******
      set member-attr "msNPAllowDialin"
   next
end
```

To configure LDAP group settings - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
      config match
         edit 1
            set server-name "ldap"
            set group-name "TRUE"
         next
      end
   next
end
```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a diag debug command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the attribute is not set but it is expected, the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Failed group matching
```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

RADIUS SSO example

A common RADIUS SSO topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. RADIUS SSO authentication was selected because it is fast and relatively easy to configure.

This section includes:

- Assumptions
- Topology
- Configuring RADIUS
- Configuring FortiGate regular and RADIUS SSO security policies
- Testing

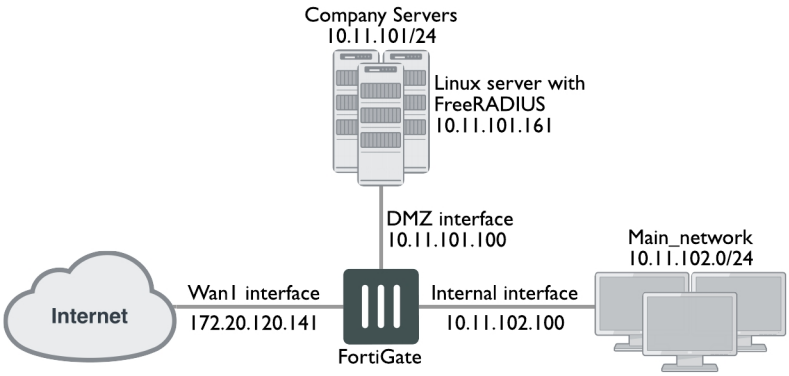
Assumptions

- VDOMs are not enabled
- The admin super_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- A RADIUS server is installed on a server or FortiAuthenticator unit and uses default attributes.
- BGP is used for any dynamic routing.
- Authentication event logging under Log&Report has been configured.

Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

RADIUS SSO topology



Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `exampledotcom_employees`. When it is all configured, the RADIUS daemon needs to started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the freeradius.org website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

Configuring FortiGate interfaces

Before configuring the RADIUS SSO security policy, configure FortiGate interfaces. This includes defining a DHCP server for the internal network as this type of network typically uses DHCP. The wan1 and dmz interfaces are assigned static IP addresses and do not need a DHCP server.

FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	No	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

To configure FortiGate interfaces - web-based manager:

1. Go to **System > Network > Interfaces**.
2. Select wan1 to edit.
3. Enter the following information and select **OK**.

Alias	Internet
Addressing Mode	Manual
IP/Network Mask	172.20.120.141/255.255.255.0
Administrative Access	HTTPS, SSH
Enable DHCP Server	Not selected
Comments	Internet
Administrative Status	Up

4. Select dmz to edit.
5. Enter the following information and select **OK**.

Alias	Servers
Addressing Mode	Manual
IP/Network Mask	10.11.101.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING, SNMP
Enable DHCP Server	Not selected
Listen for RADIUS Accounting Messages	Select
Comments	Servers
Administrative Status	Up

6. Select internal to edit.
7. Enter the following information and select **OK**.

Alias	Internal network
Addressing Mode	Manual
IP/Network Mask	10.11.102.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING
Enable DHCP Server	Select
Address Range	10.11.102.110 - 10.11.102.250
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Comments	Internal network
Administrative Status	Up

Configuring a RADIUS SSO Agent on the FortiGate unit

To create a RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.
   The Single Sign-On agent is named RSSO_Agent.

Creating a RADIUS SSO user group

To define a local user group for RADIUS SSO:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

Configuring FortiGate regular and RADIUS SSO security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both RADIUS SSO and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

Security policies required for RADIUS SSO

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	RADIUS SSO	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit policy denying all traffic that hasn't been matched.

The RADIUS SSO policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the RADIUS SSO does not mistakenly match a banned user or IP address.

This section includes:

- Schedules, address groups, and services groups
- Configuring regular security policies
- Configuring RADIUS SSO security policy

Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more information on firewall related details, see

Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

Address groups

The following address groups need to be configured before the security policies.

Address Group Name	Interface	Address range included
internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Service Group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
user_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

Configuring regular security policies

Regular security policies allow or deny access for non-RADIUS SSO traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

To configure regular security policies - web-based manager:

1. Go to **Policy & Objects > Policy > IP4**, and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_network_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	ON
Comments	Essential network services

3. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	dmz
Source Address	company_servers
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_server_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Company servers accessing the Internet

4. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	dmz
Destination Address	company_servers
Schedule	always
Service	all
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Access company servers

Configuring RADIUS SSO security policy

The RADIUS SSO policy allows access for members of specific RADIUS groups.

To configure RADIUS SSO security policy:

1. Go to **Policy & Objects > Policy > IP4**.
2. Select **Create New**.
3. Enter the following information:

Incoming Interface	Internal
Source Address	internal_network
Source User(s)	Select the user groups you created for RSSO.
Outgoing Interface	wan1
Destination Address	all
Schedule	business_hours
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, WebFilter, IPS, and Email Filter. In each case, select the default profile.

4. Select **OK**.
5. To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
6. Select **OK**.

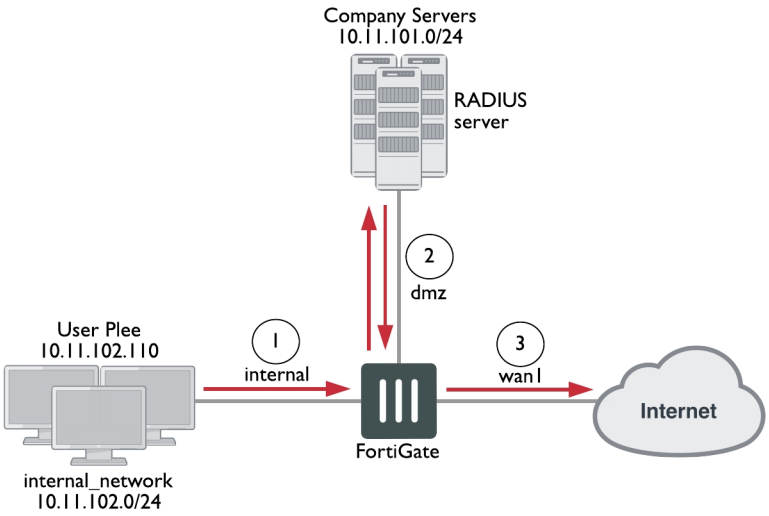
Testing

Once configured, a user only needs to log on to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

To test the configuration perform the following steps:

1. Have user 'plee' logon to their PC, and try to access an Internet website.
2. The FortiGate unit will contact the RADUS server for user plee's information.
   Once confirmed, plee will have access to the website.
   Each step generates log entries that enable you to verify that each step was successful.
3. If a step is unsuccessful, confirm that your configuration is correct.

RADIUS SSO test



Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page (**Policy > Policy**). This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens. For more information about authentication security policies, see "Authentication in security policies".

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

```
diag firewall iprope list
```

Shows the IP that the computer connected from. This is useful to confirm authorization and VPN settings.

`diag firewall iprope clear`
Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

`diag rsso query ip`
`diag rsso query rsso-key`
Queries the RSSO database.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the FortiOS Handbook Troubleshooting guide for general troubleshooting information.

Chapter 5 - Best Practices

Overview

This FortiGate Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGate units in a customer environment. It is updated periodically as new issues are identified.

General Considerations

1. For security purposes, NAT mode is preferred because all of the internal or DMZ networks can have secure private addresses. NAT mode policies use network address translation to hide the addresses in a more secure zone from users in a less secure zone.
2. Use virtual domains (VDOMs) to group related interfaces or VLAN subinterfaces. Using VDOMs will partition networks and create added security by limiting the scope of threats.
3. Use Transparent mode when a network is complex and does not allow for changes in the IP addressing scheme.

Customer service and technical support

For antivirus and attack definition updates, firmware updates, updated product documentation, technical support information, and other resources, please visit the Fortinet Technical Support web site at http://support.fortinet.com.

You can also register Fortinet products and service contracts from http://support.fortinet.com and change your registration information at any time.

For information about our priority support hotline (live support), see http://support.fortinet.com.

When requesting technical support, please provide the following information:

- Your name, and your company's name and location
- Your email address and/or telephone number
- Your support contract number (if applicable)
- The product name and model number
- The product serial number (if applicable)
- The software or firmware version number
- A detailed description of the problem

Fortinet Knowledge Base

The most recent Fortinet technical documentation is available from the Fortinet Knowledge Base. The knowledge base contains short how-to articles, FAQs, technical notes, product and feature guides, and much more. Visit the Fortinet Knowledge Base at http://kb.fortinet.com.

Comments on Fortinet technical documentation

Please send information about any errors or omissions in this document, or any Fortinet technical documentation, to techdoc@fortinet.com.

System and performance

By implementing the following best practices for system and performance, you will ensure maximum efficiency of your FortiGate device. Be sure to read everything carefully, particularly the section that concerns shutting down the FortiGate system, in order to avoid potential hardware issues.

Performance

- Disable any management features you do not need. If you don't need SSH or SNMP, disable them. SSH also provides another possibility for would-be hackers to infiltrate your FortiGate unit.
- Put the most used firewall rules to the top of the interface list.
- Log only necessary traffic. The writing of logs, especially if to an internal hard disk, slows down performance.
- Enable only the required application inspections.
- Keep alert systems to a minimum. If you send logs to a syslog server, you may not need SNMP or email alerts, making for redundant processing.
- Establish scheduled FortiGuard updates at a reasonable rate. Daily updates occurring every 4-5 hours are sufficient for most situations. In more heavy-traffic situations, schedule updates for the evening when more bandwidth can be available.
- Keep security profiles to a minimum. If you do not need a profile on a firewall rule, do not include it.
- Keep VDOMs to a minimum. On low-end FortiGate units, avoid using them if possible.
- Avoid traffic shaping if you need maximum performance. Traffic shaping, by definition, slows down traffic.

Shutting down

Always shut down the FortiGate operating system properly before turning off the power switch to avoid potentially catastrophic hardware problems.

To power off the FortiGate unit - web-based manager:

1. Go to **System > Status**.
2. In the **System Resources** widget, select **Shutdown**.

To power off the FortiGate unit – CLI:

```
execute shutdown
```

Once this has been done, you can safely turn off the power switch or disconnect the power cables from the power supply.

Migration

Network administrators are often reluctant to change firewall vendors due to the perception that the migration process is difficult. Indeed, there is no point hiding the fact that moving to a new vendor requires careful consideration. But concern over the potential pain of migration should not stand in the way of adopting new security technologies. The purpose of this chapter is to describe the best practices for performing such migrations and ultimately to ease the migration process itself.

Information gathering

It is always best practice to perform a full network audit prior to any migration. This should include:

- Full back up of all security systems (including switches, routers) in case a back-out needs to be performed.
- Physical and logical network diagram with visual audit

Understanding exactly where cables run in the network and verifying they are all correctly labeled is essential to avoid mistakes and unnecessary downtime during the upgrade. Don't overlook simple things such as:

- Do I have enough spare interfaces on my switches?
- Do I have the right fiber (single/multi mode) and right connectors (LC, FC, MTRJ, SC, ST)?
- Do I have spare cables? (in the heat of the moment, it is a simple mistake to break an RJ-45 connector or damage a fiber)
- Do I have space in the rack for the new equipment?
- Do I have enough power sockets?

No matter how securely a FortiGate is configured in the network, it cannot help if it has been bypassed; visually checking where the device sits in the network in relation to other devices will ensure you are maintaining security and verify the network diagram is 'as built'. Details of all networks including subnet masks should be documented at this point to ensure that the replacement device is configured with the correct information.

Object and policy migration

Whilst we have suggested some level of manual review is included in the policy migration, it can be useful to be able to automatically migrate simply between another vendor's format and the FortiGate format. The FortiGate policy format is text based and can easily be cut and pasted into from other vendor formats however, responding to the high customer demand to migrate away from other vendors, Fortinet have released an automatic configuration migration tool at http://convert.fortinet.com to simplify this process. Supporting Cisco ACLs, PIX, ASA, Check Point, and Juniper, the Converter can securely upload and convert the policy into the Fortinet format.

Testing and validation

This is an important process and should be tested offline first wherever possible i.e. configure the policy in the lab or on a test network and verify that the required access permissions are being implemented. To really test the solution out, the FortiGate can be implemented on the live network with a different gateway IP and the selected user pointed to the new gateway. This allows a staged approach to migrating the new platform into the network ensuring that the process does not interrupt day to day operations.

Going live and obtaining feedback

If testing and validation is successful at this point, you can migrate to the new firewall either by switching IP's and removing the old devices or by changing the default gateway in DHCP. Once the firewall is in place, acceptance testing will of course need to be carried out and an iterative process of tuning undertaken to finalize the configuration.

Adding new services

The Fortinet solution will have a plethora of additional features compared to your previous vendor and it is very tempting to start switching them on but it is a good idea to wait and validate the new firewall as was previously configured before adding new functions as this simplifies testing and problem diagnosis. Finally complete the migration (don’t forget about the Plan Do Check Act Cycle) by adding any new services that were requested and learn about the multiple features you have available with the FortiGate appliance.

Environmental specifications

Keep the following environmental specifications in mind when installing and setting up your FortiGate unit.

- Operating temperature: 32 to 104°F (0 to 40°C). Temperatures may vary, depending on the FortiGate model.
- If you install the FortiGate unit in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient temperature.
  Therefore, make sure to install the equipment in an environment compatible with the manufacturer's maximum rated ambient temperature.
- Storage temperature: -13 to 158°F (-25 to 70°C). Temperatures may vary, depending on the FortiGate model.
- Humidity: 5 to 90% non-condensing.
- Air flow - For rack installation, make sure that the amount of air flow required for safe operation of the equipment is not compromised.
- For free-standing installation, make sure that the appliance has at least 1.5 in. (3.75 cm) of clearance on each side to allow for adequate air flow and cooling.

Depending on your device, the FortiGate may generate, use, and even radiate radio frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If the equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment into an outlet on a circuit different from that to which the receiver is connected.
- Consult the dealer or an experienced radio/TV technician for help.

Explosion is a serious risk if the battery is replaced by an incorrect type. Dispose of used batteries according to the instructions. To reduce the risk of fire, use only No. 26 AWG or larger UL Listed or CSA Certified Telecommunication Line Cord.

Grounding

- Ensure the FortiGate unit is connected and properly grounded to a lightning and surge protector. WAN or LAN connections that enter the premises from outside the building should be connected to an Ethernet CAT5 (10/100 Mb/s) surge protector.
- Shielded Twisted Pair (STP) Ethernet cables should be used whenever possible rather than Unshielded Twisted Pair (UTP).
- Do not connect or disconnect cables during lightning activity to avoid damage to the FortiGate unit or personal injury.

Rack mounting

- **Elevated Operating Ambient** - If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient.
  Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (Tmax) specified by the manufacturer.

- **Reduced Air Flow** - Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.
- **Mechanical Loading** - Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.
- **Circuit Overloading** - Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.
- **Reliable Earthing** - Reliable earthing of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

Firmware

Firmware upgrading and downgrading sounds pretty simple, anyone can do it, right? The mark of a professional is not that they can do something correctly, or even do it correctly over and over again. A professional works in such a way that, if anything goes wrong they are prepared and able to quickly get things back to normal. Firmware updates can go wrong just like anything else. So a real professional does things in a way that minimizes their risk and follows some best practices, as listed below.

Firmware change management

Consider the following five points when performing firmware upgrades, not only in FortiOS but in general. This applies to pretty much any change you have to do in a production environment.

Understanding the new version first

Before attempting any changes in production, first make sure you set up a laboratory where you can freely play with the new features, and understand them with enough time and no pressure. Read the Release Notes, Manuals, and other documentation like presentations, videos, or podcasts about the new version.

You are ready to explain the need for an upgrade once you understand:

- The differences and the enhancements between the new version and the previous version(s).
- The impact of the upgrade on customers and the users of the operating platform.
- The known limitations that might affect your environment.
- The potential risks when performing the upgrade.
- The licensing changes that may apply.

Never attempt to upgrade to a version you don't fully understand (both on features and known limitations), and on which you have no operational experience.

Have a valid reason to upgrade

The reason can NOT be “Because I want to have the latest version”. The reason has to be explained in terms of business, technical, and/or operational improvement.

Affirmative answers to the following questions are valid reasons to upgrade:

- Does the new version have a feature that helps to ensure compliance?
- Does the new version have an enhancement that allows 40% decrease (40% improvement) on the time to perform a certain operation?
- Does the new feature correct a known defect/bug found on a previous version that affects the company business/operations?
- Will the new version allow your organization to deploy new services that will help to gain new customers or increase loyalty of existing ones?
- Is the vendor cutting support for the version your organization is currently using?

If the best reason to upgrade is “Because the new features seem to be cool” or “Because I want to have the latest version”, a little more understanding and planning may be necessary.

Prepare an upgrade plan

If you choose to upgrade because you found a valid reason to do so, make sure you create a plan that covers business, technical, and operational aspects of the upgrade:

Business:

Proper planning and justification for an upgrade should be proportional to how critical the system is to the business.

- Make sure you can clearly articulate the benefits of the upgrade in business terms (time, money, and efficiency).
- Understand the business processes that will be affected by the change.
- Make sure the upgrade maintenance window is not close to a business-critical process (such as quarterly or monthly business closure).
- Obtain executive and operational approval for the maintenance window. The approval must come from the owners of ALL the systems/information affected by the upgrade, not only from those that own the system being upgraded. The approval must be done in a formal (written or e-mail) form.

Technical and operational:

- Re-read the Release Notes for the technology you are upgrading. Supported hardware models, upgrade paths, and known limitations should be clearly understood.
- Make sure your upgrade maintenance window does not overlap with any other maintenance window on your infrastructure.
- If you have any premium support offer (such as TAM, Premium Support), do a capacity planning exercise to ensure the new firmware/software version does not take more hardware resources than you currently have.
- Create a backup, whether or not you have scheduled backups. Create a new fresh backup.
- Obtain offline copies of both the currently installed firmware and the new version.
- Create a list of systems with inter-dependencies to the system you are upgrading. For example, if you are upgrading a FortiGate; understand the impact on any FortiAP, FortiAuthenticator, FortiToken, FortiManager, or FortiAnalyzer you have on your environment.
- Ensure you have a list of adjacent devices to the upgrading platform and have administrative access to them, just in case you need to do some troubleshooting. Are you upgrading FortiWeb? Make sure you can administratively access the Web Applications. Are you upgrading a FortiGate? Make sure you can administratively access the surrounding switches and routers.
- Have a step-by-step plan on how to perform and test the upgrade. You want to make sure you think of the worst situation before it happens, and have predefined courses of action, instead of thinking under pressure when something already went wrong.
- Define a set of tests (that include critical business applications that should be working) to make sure the upgrade went fine. If any test does not go well, define which ones mandate a rollback and which ones can be tolerated for further troubleshooting. This set of tests should be run before and after the upgrade to compare results, and they should be the same.
- Define a clear rollback plan. If something goes wrong with the upgrade or the tests, the rollback plan will help you get your environment back to a known and operational status. The plan must clearly state the conditions under which the rollback will be started.

- Declare configuration freezes. A little bit before and after the upgrade. The idea is to reduce the amount of variables to take into consideration if something goes wrong.
- Perform a “Quality Assurance” upgrade. Grab a copy of the production configuration, load it on a non-production box and execute the upgrade there to see if there are any issues on the process. Then adjust your plan according to the results you obtained.
- Have a list of information elements to be gathered if something goes wrong. This ensures that, even if the upgrade fails, you will collect enough information so you can troubleshoot the issue without needing to repeat the problem. Get help from TAC/Support departments if you need to check what else could be missing on your list.
- Define a test monitoring period after the change was completed. Even if the upgrade went smoothly, something could still go wrong. Make sure you monitor the upgraded system for at least one business cycle. Business cycles may be a week, a month, or a quarter, depending on your organization’s business priorities.

Execute the upgrade plan

Execution of an upgrade is just as key as planning.

Once you are performing the upgrade, the pressure will rise and stress might peak. This is why you should stick to the plan you created with a cool head.

Resist the temptation to take decisions while performing the upgrade, as your judgment will be clouded by the stress of the moment, even if a new decision seems to be “obvious” at such time. If your plan says you should rollback, then execute the rollback despite the potential “We-can-fix-this-very-quickly” mentality.

While performing the upgrade, make sure all the involved components are permanently monitored before, during, and after the upgrade, either via monitoring systems, SNMP alerts, or at least with tools like a ping. Critical resources like CPU, memory, network, and/or disk utilization must also be constantly monitored.

To avoid misunderstandings, when performing the tests for each critical application defined on the planning, make sure there are formal notifications on the results for each user area, service, system, and/or application tested.

Regardless if you have to rollback or not, if a problem occurs, make sure you gather as much information about the problem as possible, so you can later place a support ticket to find a solution.

Last but not least, document the upgrade:

- Enable your terminal emulation program to leave trace of all the commands executed and all the output generated. If you are performing steps via GUI, consider using a video capture tool to document it.
- Document any command or change performed over the adjacent/interdependent systems. Make sure they are acknowledged by the relevant administrators
- Document any deviations performed over the upgrade plan. This is planned-versus-actual.

Learn more about change management

Change Management and Change Control are huge knowledge areas in the field of Information Systems and Computer/Network Security.

This document is by no means a comprehensive list on what you should do when performing an upgrade, with either Fortinet or any other technology. It is merely a list of important things you should take into consideration when performing upgrades which are the result of years of experience dealing with changes on critical environments, as it is common that security devices are protecting critical applications and processes.

There are vast resources on the topic: books, public white papers, blog entries, etc. If you search the Internet for the “Change Control Best Practices” or “Change Management Best Practices” you will get many interesting documents.

Changes on production IT infrastructure are critical to the business. Make sure they play in your favor and not against you.

Performing a firmware upgrade

Upgrading a firewall is something that should be compared to upgrading the operating system on your computer. It’s not to be taken lightly! You want to make sure everything is backed up and you have some options available if things go awry. Assuming it all seems to work you also want a list of things to do in order to confirm everything is working properly. Finally, you need enough time to do it. All really simple stuff, but what does this mean in relation to upgrading your FortiGate? It means, you follow these simple steps:

1. **Backup and store old configuration (full configuration backup from CLI).**
   Digging into this a little, step 1 is easy to understand. Do a full backup of your old configuration. This is all part of your disaster recovery plan. If the upgrade fails in some way you need to make sure you can get the Firewall back up and running. The best way to do this is to get it back to a state where you know what the behavior was. For more information, refer to "Performing a configuration backup" on page 627.
2. **Have copy of old firmware available.**
   Step 2, is also part of your disaster recovery. If the upgrade fails you might be able to switch the active partition. But as a Professional, you need to be prepared for the worst case scenario where you can’t do that. Which means you’ll need your old firmware.
3. **Have disaster recovery option on standby -- especially if remote.**
   Step 3, is your plan for what to do in the event of a critical failure. As we’re talking FortiGate this means that your firewall doesn’t come back after the upgrade. What this means is that you need to be able to get to the console port in order to find out why. Maybe it’s DHCP and the IP changed, maybe the OS is corrupt, who knows? Get to the console and find out.
   There could be a simple fix. If there’s not, then be prepared for a format and TFTP reload.
4. **Read the release notes, including the upgrade path and bug information.**
   Step 4, READ THE RELEASE NOTES. They contain all kinds of information, known bugs, fixed bugs even upgrade issues like lost configuration settings. Not all upgrade information is ever contained in any products release notes. That does not mean they are devoid of good/useful information. Read them, digest them, then a few days later read them again.
5. **Double check everything.**
   Step 5, do a double check of everything. Is your TFTP server working, does your console connection function, is there anything in the release notes that could impact your upgrade procedure, do you have your configuration backed up? Make sure you’ve done everything.
6. **Upgrade.**
   Step 6, do the upgrade. Doing an upgrade doesn’t take very long, a few minutes (less a lot of times) but make sure you schedule enough time for it. At the end of the day an upgrade can succeed or fail. If it succeeds you want some time to check/confirm that any important features you have are working (VPNs etc). If it fails you’ll need time to sort things out.

Performing a firmware downgrade

Just like upgrading, you need to make sure it's done properly. While similar, the steps are somewhat different since there are other pitfalls in this case.

1. **Locate pre-upgrade configuration file.**
   Step 1 is very important. This is why, when you upgrade you make a backup of your old configuration and save it. If you don't, then you'll need to rebuild manually.
2. **Have copy of old firmware available.**
   Step 2 is fairly obvious. Even with devices that have multiple partitions and your downgrade process is simply going to be to switch the active partition, this could go wrong. In which case, you may be without Internet access. A professional has a plan for when things go wrong.
3. **Have disaster recovery option on standby -- especially if remote.**
   Step 3 is no different from before. Hopefully you don't need to format the unit, but be prepared for that, just in case.
4. **Read the release notes -- is a downgrade possible, or necessary?**
   Step 4, once again, is to READ THE RELEASE NOTES. In this case, you will need to do this for the version you are on, and the version you are downgrading too, and everything in between (if you are going back multiple major releases or patches). Maybe the OS switched from 32 to 64 bits somewhere between the two firmware releases. In order to make sure you don't get nailed by something like that you need to check the upgrade and downgrade information in every major release and patch, as it may have a direct impact on your options.
5. **Double check everything.**
6. **Downgrade -- all settings, except those needed for access, are lost.**
   Step 5 and 6 are the same as before. Double check everything, then downgrade.
7. **Restore pre-upgrade configuration.**
   Step 7 is new. Obviously most settings are lost when you downgrade so in order to get back up and running you will need to restore your old configuration file.

Performing a configuration backup

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

It is also recommended that once any further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site.The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

To back up the FortiGate configuration - web-based manager:

1. Go to **System > Dashboard > Status**.
2. On the **System Information** widget, select **Backup** next to **System Configuration**.
3. Select to backup to your **Local PC** or to a **USB Disk**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.
   Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

To back up the FortiGate configuration - CLI:

```
execute backup config management-station <comment>
```

… or …

```
execute backup config usb <backup_filename> [<backup_password>]
```

… or for FTP (note that port number, username are optional depending on the FTP site)…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
    [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
   edit <vdom_name>
```

Backing up a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for and administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global
   set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
   set admin-scp enable
end
```

```
config vdom
   edit <vdom_name>
```

Security Profiles (AV, Web Filtering etc.)

Infection can come from many sources and have many different effects. Because of this, there is no single means to effectively protect your network. Instead, you can best protect your network with the various UTM tools your FortiGate unit offers.

Firewall

- Be careful when disabling or deleting firewall settings. Changes that you make to the firewall configuration using the GUI or CLI are saved and activated immediately.
- Arrange firewall policies in the policy list from more specific to more general. The firewall searches for a matching policy starting from the top of the policy list and working down. For example, a very general policy matches all connection attempts. When you create exceptions to a general policy, you must add them to the policy list above the general policy.
- Avoid using the All selection for the source and destination addresses. Use addresses or address groups.
- If you remove all policies from the firewall, there are no policy matches and all connections are dropped.
- If possible, avoid port ranges on services for security reasons.
- The settings for a firewall policy should be as specific as possible. Do not use 0.0.0.0 as an address. Do not use Any as a service. Use subnets or specific IP addresses for source and destination addresses and use individual services or service groups.
- Use a 32-bit subnet mask when creating a single host address (for example, 255.255.255.255).
- Use logging on a policy only when necessary and be aware of the performance impact. For example, you may want to log all dropped connections but can choose to use this sparingly by sampling traffic data rather than have it continually storing log information you may not use.
- It is possible to use security policies based on 'any' interface. However, for better granularity and stricter security, explicit interfaces are recommended.
- Use the comment field to input management data, for example: who requested the rule, who authorized it, etc.
- Avoid FQDN addresses if possible, unless they are internal. It can cause a performance impact on DNS queries and security impact from DNS spoofing.
- For non vlan interfaces, use zones (even if you have only one single interface for members) to allow:
  - An explicit name of the interface to use in security policies ('internal' is more explicit than 'port10').
  - A split between the physical port and its function to allow port remapping (for instance moving from a 1G interface to a 10G interface) or to facilitate configuration translation, as performed during hardware upgrades.

Security

- Use NTP to synchronize time on the FortiGate and the core network systems, such as email servers, web servers, and logging services.
- Enable log rules to match corporate policy. For example, log administration authentication events and access to systems from untrusted interfaces.
- Minimize adhoc changes to live systems, if possible, to minimize interruptions to the network. When not possible, create backup configurations and implement sound audit systems using FortiAnalyzer and FortiManager.
- If you only need to allow access to a system on a specific port, limit the access by creating the strictest rule possible.

Authentication

- You must add a valid user group to activate the Authentication check box on the firewall policy configuration page.
- Users can authenticate with the firewall using HTTP or FTP. For users to be able to authenticate, you must add an HTTP or FTP policy that is configured for authentication.

Antivirus

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure you receive antivirus signature updates as soon as they are available.
- To ensure that all AV push updates occur, ensure you have an AV profile enabled in a security policy.
- Enable only the protocols you need to scan. If you have antivirus scans occurring on the SMTP server, or use FortiMail, it is redundant to have scanning occur on the FortiGate unit as well.
- Reduce the maximum file size to be scanned. Viruses usually travel in small files of around 1 to 2 megabytes.
- Do not quarantine files unless you regularly monitor and review them. This is otherwise a waste of space and impacts performance.
- Examine antivirus reports and log messages periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.

Antispam

- If possible use, a FortiMail unit. The antispam engines are more robust.
- Use fast DNS servers.
- Use specific security profiles for the rule that will use antispam.
- DNS checks may cause false positive with HELO DNS lookup.
- Content analysis (banned words) may impose performance overhead.

Intrusion Prevention System (IPS)

Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions. Refer to the following list of best practices regarding IPS.

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive IPS signature updates as soon as they are available.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Create and use security profiles with specific signatures and anomalies you need per-interface and per-rule.
- Do not use predefined or generic profiles. While these profiles are convenient to supply immediate protection, you should create profiles to suit your network environment.

- If you do use the default profiles, reduce the IPS signatures/anomalies enabled in the profile to conserve processing time and memory.
- If you are going to enable anomalies, make sure you tune thresholds according to your environment.
- If you need protection, but not audit information, disable the logging option.
- Tune the IP-protocol parameter accordingly.

Blocking Skype using CLI options for improved detection

If you want to identify or block Skype sessions, use the following CLI command with your FortiGate's public IP address to improve detection (FortiOS 4.3.12+ and 5.0.2+):

```
config ips global
   set skype-client-public-ipaddr 198.51.100.0,203.0.113.0
end
```

Note that the above syntax is configured using multiple public IP addresses, where a single public IP address may suffice depending on your network configuration.

Email filter

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine.

- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to the FortiGuard AntiSpam Service.

URL filtering

Best practices for URL filtering can be divided into four categories: flow-based versus proxy based filtering; local category/rating feature; URL filter 'Exempt' action; and Deep Scan.

Flow-based versus proxy-based

Try to avoid mixing flow-based and proxy-based features in the same profile if you are not using IPS or Application Control.

Local category/rating feature

Local categories and local rating features consume a large amount of CPU resources, so use this features as little as possible. It is better to use Local categories instead of using the 'override' feature, since the 'override' feature is more complicated and more difficult to troubleshoot.

URL filter 'Exempt' action

When using the URL filter 'Exempt' option, all scans (including antivirus) are bypassed by default, so use this option only for trusted sites.

Configuration notes: You need to configure 'Exempt' actions in the URL filter if you want to bypass the FortiGuard Web Filter.You can configure which particular inspection(s) you want to bypass using the `set exempt` command in `config webfilter urlfilter`.

Deep Scan

The 'Deep Scan' feature is much heavier on resources than 'HTTPS URL Scan Only'. Deep Scan is much more accurate, since many sites (such as various Google applications) cannot be scanned separately without deep scanning enabled.

Note: If you configre Deep Scan in the SSL profile and then configure 'Enable HTTPS URL Scan Only' in the web filter profile, then Deep Scan is not performed.

Web filtering

FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous

Patch management

When vulnerabilities are discovered in software, the software vendors release updates that fix these problems. Keeping your software and operating system up-to-date is a vital step to prevent infection and defend against attacks.

- Follow the latest advisories and reports on the FortiGuard webpage.
- Apply updates to all software as the updates become available.
- FortiGuard Vulnerability Management can help identify security weaknesses in your network. This subscription service is available through FortiScan and FortiAnalyzer units.
- Apply firmware updates to your FortiGate unit as they are released.
- Subscribe to FortiGuard AntiVirus and IPS services, so that AntiVirus and IPS scanning engines are automatically updated when new version are released.

Policy configuration

Configuring the FortiGate unit with an 'allow all' traffic policy is very undesirable. While this does greatly simplify the configuration, it is less secure. As a security measure, it is best practice for the policy rulebase to 'deny' by default, and not the other way around.

Policy configuration changes

On a heavy-loaded system, plan configuration changes during low usage periods in order to minimize impact on CPU usage and established sessions. In this scenario, it is considered a best practice to de-accelerate the hardware-accelerated sessions.

You can configure de-accelerated behaviour on hardware-accelerated sessions using CLI commands to control how the processor manages policy configuration changes. The following CLI commands are to be used:

```
config system settings
   set firewall-session-dirty { check-all | check-new | check-policy-option }
end
```

where you want the following to be true:

`check-all`	CPU flushes all current sessions and re-evaluates them. This is the default option.
`check-new`	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
`check-policy-option`	Use the option selected in the `firewall-session-dirty` field of the firewall policy (`check-all` or `check-new`, as above, but per policy).

Policy whitelisting

- Allow only the necessary inbound and outbound traffic.
- If possible, limit traffic to specific addresses or subnets. This allows the FortiGate unit to drop traffic to and from unexpected addresses.

IPS and DoS policies

- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to Block.
- DoS attacks are launched against vulnerabilities. Maintain a FortiGuard IPS subscription to ensure your FortiGate unit automatically receives new and updated IPS signatures as they are released.
- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received. The key is to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, but your network may require very different values. One way to find the correct values for your environment is to set the action to Pass and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

Networking

When configuring your network, ensure that there is no 'back door' access to the protected network. For example, if there is a wireless access point, it must be appropriately protected with password and encryption.

Be sure to also maintain an up-to-date network diagram which includes IP addressing, cabling, and network elements.

Routing configuration

- Always configure a default route.
- Add blackhole routes for subnets reachable using VPN tunnels. This ensures that if a VPN tunnel goes down, traffic is not mistakingly routed to the Internet unencrypted.

Policy routing

Keep the number of policy routes to a minimum to optimize performance in route lookup and to simplify troubleshooting.

Dynamic routing

- Select a Router ID that matches an IP assigned to an interface. This avoids the likelihood of having two devices with the same router ID.
- For routing over an IPsec tunnel, assign IP addresses to both ends of the tunnel.

Advanced routing

Use the following best practices for advanced routing when dealing with Border Gateway Protocol (BGP) and Open Shortest Path First (OSPF).

Border Gateway Protocol (BGP)

If you are using BGP, it is recommended that you enable soft-reconfiguration. This has two benefits:

- It allows you to perform 'soft clear' of peers after a change is made to a BGP policy.
- It provides greater visibility into the specific prefixes learned from each neighbor.

Leave soft-reconfiguration disabled if your FortiGate does not have much unused memory. Soft-reconfiguration requires keeping separate copies of prefixes received and advertised, in addition to the local BGP database.

Open Shortest Path First (OSPF)

- Avoid use of passive interfaces wherever possible.
- Avoid use of virtual links to connect areas. All areas should be designed to connect directly to the backbone area.
- Ensure that all backbone routers have a minimum of two peering connections to other backbone neighbors.
- An entire OSPF domain should be under common administration.

Network Address Translation (NAT)

- Beware of misconfiguring the IP Pool range. Double-check the start and end IPs of each IP pool. The IP pool should not overlap with addresses assigned to FortiGate interfaces or to any hosts on directly connected networks.
- If you have internal and external users accessing the same servers, use split DNS to offer an internal IP to internal users so that they don't have to use the external-facing VIP.

Configuring NAT

Do not enable NAT for inbound traffic unless it is required by an application. If, for example, NAT is enabled for inbound SMTP traffic, the SMTP server might act as an open relay.

Transparent Mode

- Do not connect two ports to the same VLAN on a switch or to the same hub. Some Layer 2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN.
- If you operate multiple VLANs on your FortiGate unit, assign each VLAN id to its own forwarding domain to ensure that the scope of the broadcast does not extend beyond the VLAN it originated in.

To protect against Layer 2 loops:

- Enable `stpforward` on all interfaces.
- Use separate VDOMs for production traffic (TP mode VDOM) and management traffic (NAT/Route mode VDOM).
- Only place those interfaces used for production in the TP mode VDOM. Place all other interfaces in the NAT/Route mode VDOM. This protects against potential Layer 2 loops.

Using Virtual IPs (VIPs)

- Use the external IP of 0.0.0.0 when creating a VIP for a FortiGate unit where the external interface IP address is dynamically assigned.
- Be sure to select the correct external interface when creating a new virtual IP (VIP). The external interface should be set to the interface at which the FortiGate unit receives connection requests from external networks.

FGCP High Availability

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling session pickup delay to improve performance by reducing the number of sessions that are synchronized.
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces.
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.

  - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See Enabling or disabling HA heartbeat encryption and authentication.
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NPx processor to avoid NPx-related problems from affecting heartbeat traffic.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See Remote link failover.

WAN Optimization

WAN Optimization features require significant memory resources and generate a high amount of I/O on disk. Before enabling WAN Optimization, ensure that the memory usage is not too high. If possible, avoid other disk-intensive features such as heavy traffic logging on the same disk as the one configured for WAN Optimization needs.

In general, it is preferable to enable the Transparent Mode checkbox and ensure that routing between the two endpoints is acceptable. Some protocols may not work well without enabling Transparent Mode.

Other best practices for utilizing the WAN Optimization feature follow.

Sharing the WAN Opt. tunnel for traffic of the same nature

WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic (such as CIFS traffic from different servers). However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel.

Ordering WAN Opt. rules appropriately

- Precise, port specific WAN Optimization rules should be at the top of the list.
- Generic rules, such as overall TCP, should be at the bottom of the list.

Avoiding mixing protocols in a WAN Opt. tunnel

Different protocols may be more or less talkative or interactive . Mixing protocols in a tunnel may result in a delay for some of them. It is recommended to define protocol specific wan-optimization rules and restrict the ports to the necessary ones only for performance reasons.

Setting correct configuration options for CIFS WAN Opt.

Ensure that the WAN Optimization rules cover TCP ports 139 and 445 (on the same or two different rules). Also ensure that Transparent Mode is selected.

Setting correct configuration options for MAPI WAN Opt.

For MAPI WAN Optimization, only specify a rule with TCP port 135 (unless the MAPI control port is configured differently). Derived data sessions using other random ports will be handled by the CIFS wan-optimization daemon even with only the control port configured.

Testing WAN Opt. in a lab

- Ensure that WAN emulators are used to simulate the WAN. If no WAN emulator is used, it is expected to have better results without WAN Optimization than with WAN Optimization.
- To test the difference between cold transfers (first-time transfers) and warm transfers, it is recommended to generate a random file of the cold transfer to ensure that the test is the first time that the file has been seen.

Regarding byte compression and type of file

Enabling byte compression on file transfers already compressed (.jpeg files, compressed archive, etc.) won't provide any performance increase and could be seen as a misuse of CPU resources.

Regarding network address translation (NAT)

Selecting the NAT feature in a security policy does not have any influence on WAN Optimization traffic.

High Availability

There is no benefit to using active-active mode, so for pure WAN Optimization needs, use active-passive mode. Refer to the FGCP High Availability section for other best practices related to HA.

Authentication with specific peers

Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure.

Virtual Domains (VDOMs)

VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization. This section provides a list of best practices for configuring VDOMs.

Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. It is recommended that you perform the following tasks in the order given (while you may not require all for your network topology):

1. Change the management virtual domain.
2. Configure FortiGate interfaces in a NAT/Route VDOM.
3. Configure VDOM routing.
4. Configure security policies for NAT/Route VDOMs.
5. Configure UTM profiles for NAT/Route VDOMs.
6. Test the configuration.

Virtual clustering

If you decide to disable override for clurstering, as a result of persistent renegotiating, you should disable it for both cluster units.

Explicit proxy

- For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.
- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSSO, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.
- Set the explicit web proxy and explicit FTP proxy Default Firewall Policy Action to Deny. This means that a firewall policy is required to use these explicit proxies, allowing you to control access and impose security features.
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy.

Wireless

The following section contains a list of best practices for wireless network configurations with regard to encryption and authentication, geographic location, network planning, power usage, client load balancing, local bridging, SSIDs, and the use of static IPs.

Encryption and authentication

It is best practice to always enable the strongest user authentication and encryption method that your client supports. Fortinet recommends the following security, in order of strongest to weakest:

- WPA2 - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WPA - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WEP128 - 26 Hexadecimal digit key
- WEP64 - 10 Hexadecimal digit key
- None - Open system

Geographic location

Ensure that the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

The location setting can only be changed from CLI. To change the country to France, for example, enter the following:

```
config wireless-controller setting
   set country FR
end
```

To see the list of country codes, enter a question mark ('?') in place of the country code.

Using an incorrect geographic location is a common error that can lead to unpredicable results on the client side.

Network planning

It is recommended that you perform a proper site survey prior positioning the wireless access point. In order to evaluate the coverage area environment, the following criteria must be taken into account:

- Size of coverage area
- Bandwidth required
- Client wireless capabilities

After completing a RF site survey, you'll have a good idea of the number and location of access points needed to provide users with adequate coverage and performance.

However, prior to installing the access points, be sure to determine the RF channel(s) you plan to use. This will ensure that users can roam throughout the facility with substantial performance.

To avoid co-channel interference, adjacent Wi-Fi APs must be configured to use non-overlapping channels. Otherwise, you'll find poor performance will degrade because of interference between access points.

It is recommended to statically configure the non-overlapping channels on every access point, using one Custom AP profile per AP (or group of APs). If static configuration cannot be used, the FortiOS Wi-Fi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature.

Lowering the power level to reduce RF interference

Relevant Product(s): FortiAP

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. If possible, reduce the transmitter power of your wireless access point so that the signal is not available beyond the areas where it is needed. Auto Tx Power Control can be enabled to automatically adjust the transmit power.

In cases where customers complain about slow wireless traffic through a FortiAP, it might be necessary to try to reduce the possibility of RF interference. It is best practice not to locate FortiAPs near steel beams or other interfering materials. You can try using a wireless sniffer tool to collect the wireless packets and then analyze the extent of air interference.

A common mistake is spacing FortiAPs based upon the 5Ghz radio frequency. The 2.4Ghz signal travels further.

You have two options when confronted with slow wireless traffic through a FortiAP:

Option #1: Reducing transmit power

Perform a speed test and record the results. Set one of the radios on a FortiAP to be in dedicated monitoring mode. Then observe how many APs are detected. If the number of APs is too high (i.e., greater than 20), try reducing the transmit power in the WTP profile for the FortiAPs until the number of dedicated APs has dropped significantly.

Repeat the speed test.

Option #2: Ensuring that VAPs are distributed over the available channels

No built-in tools are available to measure RF interference directly. However, FortiOS 5.0 does allow for automatic power adjustment, which should minimize the occurrence of RF interference.

Wireless client load balancing

Wireless load balancing allows your wireless network to more efficiently distribute wireless traffic among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- **Access Point Hand-off** - The wireless controller signals a client to switch to another access point.
- **Frequency Hand-off** - The wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Local bridging

Whenever possible, use local bridging to offload the CAPWAP tunnel. Note that in this case, Wi-Fi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN. The vlan ID can only be configured

from the CLI:

```
config wireless-controller vap
   edit "vaplocalbridge"
      set vdom "root"
      set ssid "testvaplocalbridge"
      set local-bridging enable
      set vlanid 40 ---> only available in CLI
   next
end
```

Advertising SSIDs

- It is highly recommended to advertise the SSID. It makes it easier for customers and wireless clients. Also, if you 'hide' the SSID (known as ‘network cloaking’), then clients will always look for it when they're outside the coverage area, which searches for known SSIDs, in effect leaking the SSID anyway. Refer to RFC 3370. Furthermore, many of the latest Broadcom drivers do not support hidden SSID for WPA2.
- For security reason, you might want to prevent direct communication between your wireless clients. In this case, enable Block Intra-SSID Traffic (in the SSID configuration).
- In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > WiFI Network > SSID** to change the SSID. Fortinet also recommends that you create a new preshared key instead of using the default.

Using static IPs in a CAPWAP configuration

In a large FortiAP deployment with more than 20 FortiAPs connecting to a Fortigate Wireless Controller (AC), it is recommended to use static IPs on the access points instead of DHCP, setting the AC IP statically and the AC discovery type to static (Type 1), instead of learning it through broadcast, multicast, or DHCP.

This makes management of the APs easier since you know the exact IP of each access point. Troubleshooting also becomes easier as the debug of the AC controller won’t continuously attempt the different discovery methods in sequence (broadcast > multicast > static).

Logging and reporting

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- What FortiGate activities you want and/or need logged (for example, security features).
- The logging device best suited for your network structure.
- If you want or require archiving of log files.
- Ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

- Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
- Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
- If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the IM usage dashboard widget or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
- Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

- When downloading log messages and viewing them on a computer, the log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.

System memory and hard disks

If the FortiGate unit has a hard disk, it is enabled by default to store logs. This also means that you do not have to enable this and configure the settings for logging to the hard disk, but modify these settings so that it is configured for your network logging requirements.

If the FortiGate unit has only flash memory, disk logging is disabled by default, as it is not recommended. Constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. It must be enabled in the CLI under config log disk setting.

For some low-end models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Chapter 6 - FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

Overview of FortiOS Carrier features provides an overview of the three major topics for FortiOS Carrier — Dynamic Profiles, MMS, and GTP.

Carrier web-based manager settings describes the web-based manager interface of FortiOS Carrier specific features.

MMS Security features describes FortiOS security features as they apply to MMS including MMS virus scanning, MMS file filtering, MMS content-based Antispam protection, and MMS DLP archiving.

Message flood protection describes setting thresholds to protect your MMS servers from receiving too many messages from the same sender.

Duplicate message protection describes setting thresholds to protect your MMS servers from receiving the same message from more than one sender.

Configuring GTP on FortiOS Carrier explains configuration of the more basic FortiOS Carrier GTP features.

GTP message type filtering explains this feature, and how to configure it on FortiOS Carrier.

GTP identity filtering explains this feature, and how to configure it on FortiOS Carrier.

Troubleshooting provides answer to common FortiOS Carrier GTP issues.

Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

All FortiGate units, carrier-enabled or not, are capable of handling Stream Control Transmission Protocol (SCTP) traffic, which is a protocol designed for and primarily used in Carrier networks.

This section includes:

Overview
Registering FortiOS Carrier
MMS background
How FortiOS Carrier processes MMS messages
MMS protection profiles
Bypassing MMS protection profile filtering based on carrier endpoints
Applying MMS protection profiles to MMS traffic
GTP basic concepts
GPRS network common interfaces
Packet flow through the GPRS network
SCTP

Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks: MMS and GTP.

MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7. See “MMS background”.

GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 and GTPv2.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See GTP basic concepts.

Registering FortiOS Carrier

A license is purchased from Fortinet, and is delivered by mail as a scratch card. The contained registration code is entered into the CLI according to the instructions on the card. The FortiGate unit will then factory reset itself into Carrier mode.

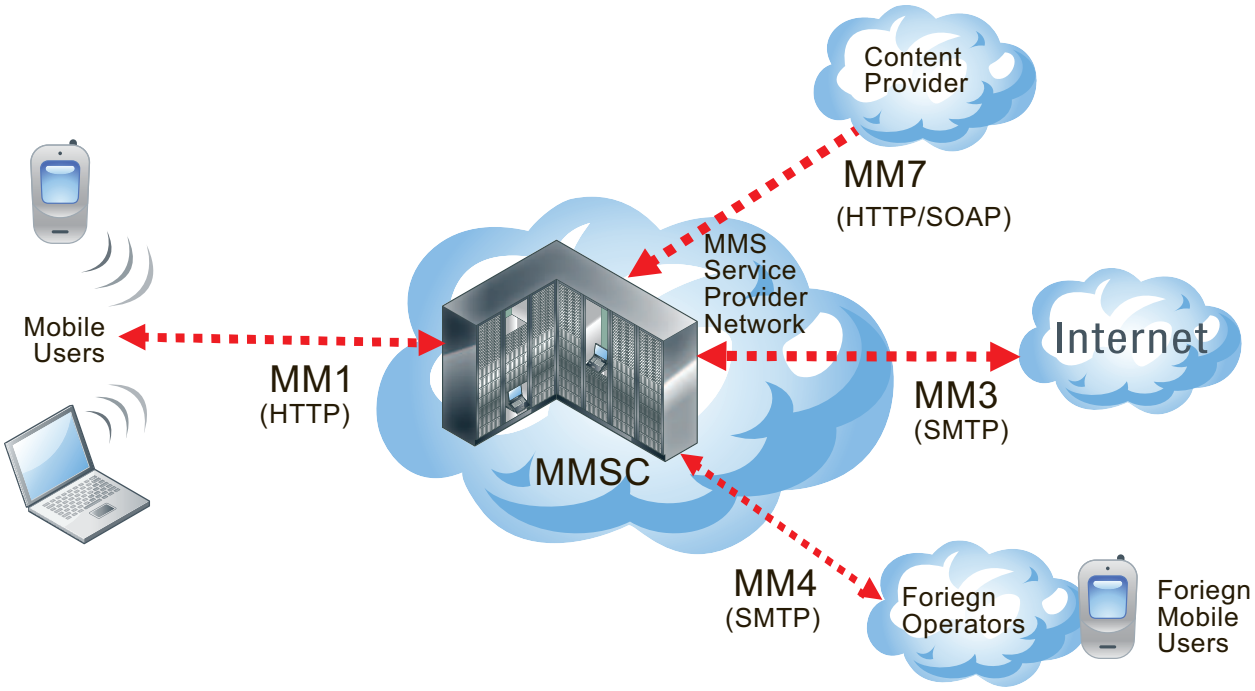
Only certain FortiGate models support Carrier mode. Contact Fortinet Support for more information and firmware images.

MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

MMS content interfaces



MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foriegn service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

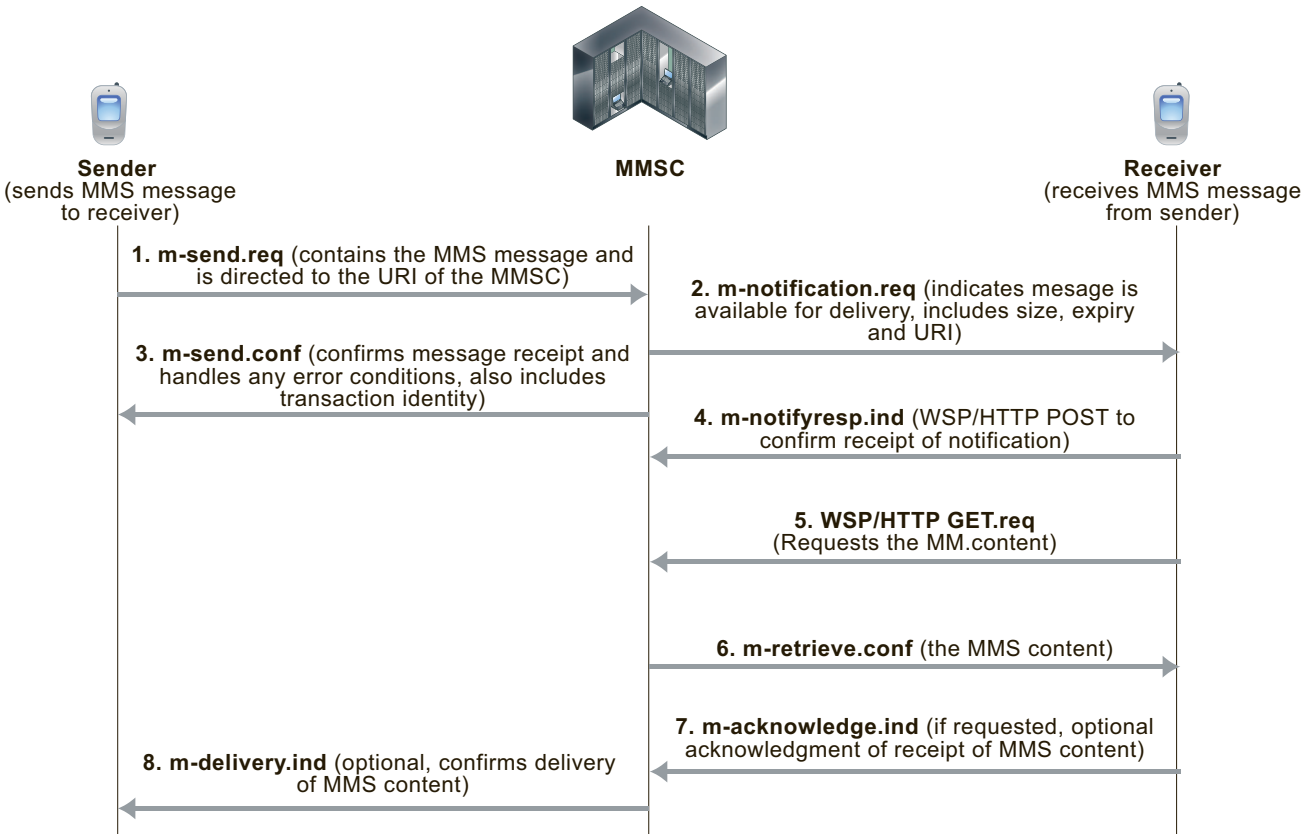
MMS content interfaces

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

How MMS content interfaces are applied

As shownbelow, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

MM1 transactions between senders and receivers and the MMSC

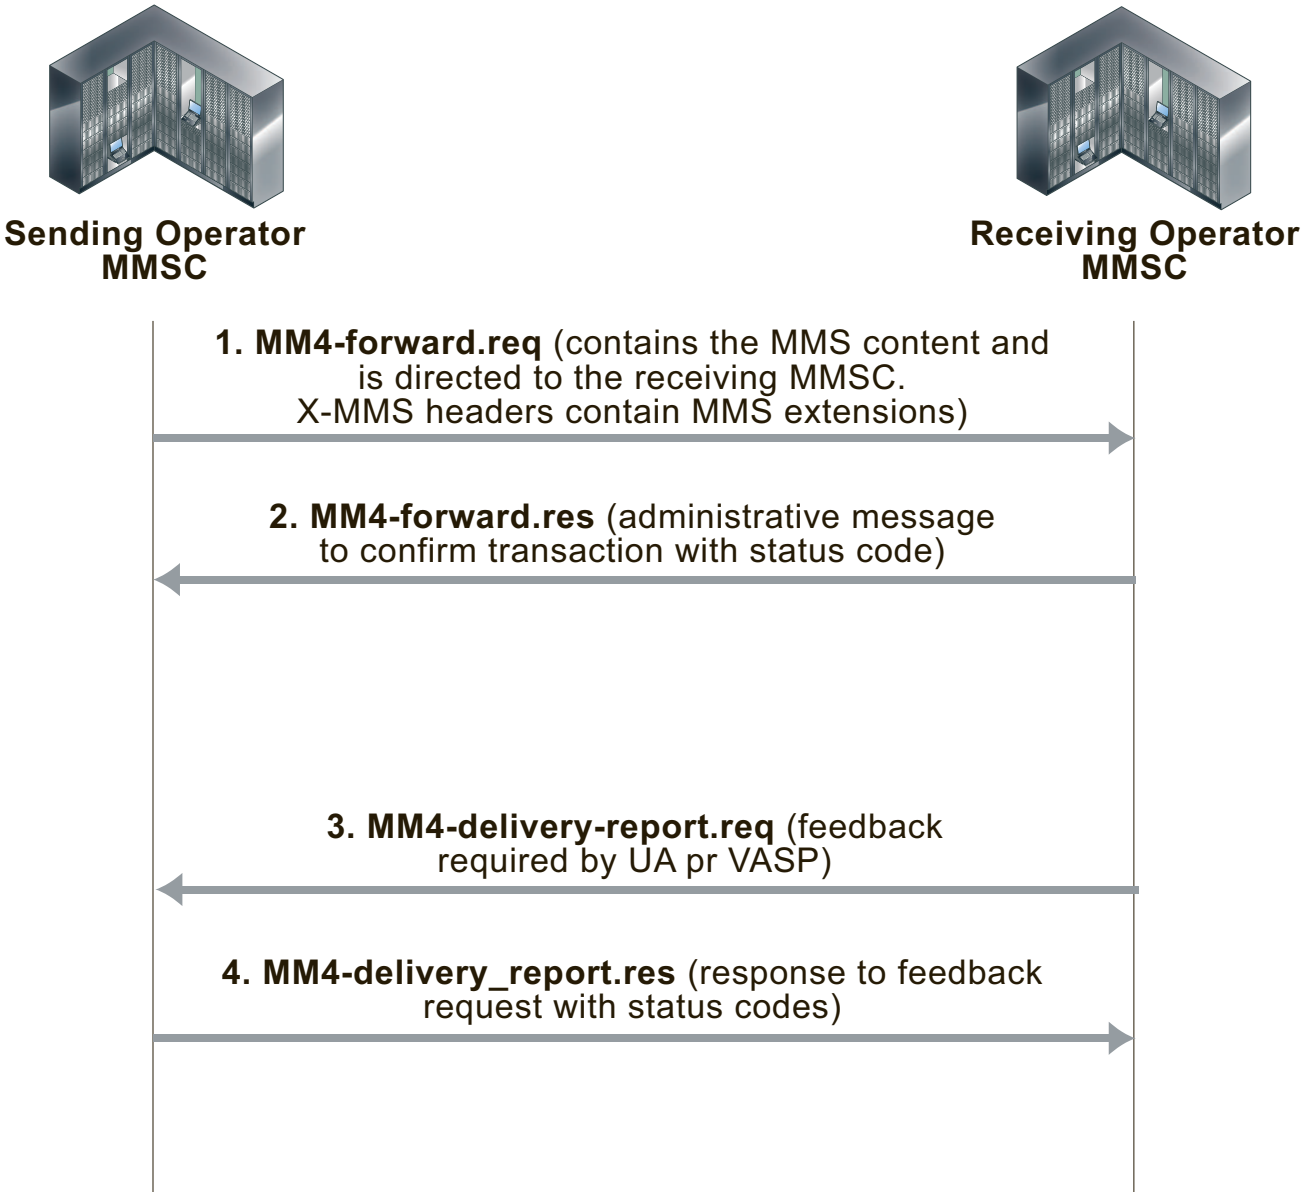


If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see the figure below).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC. This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

MM4 messages sent between operator MMSCs



This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

The method for determining whether a handset is MMS capable is not specified by the standards. A database is usually maintained by the operator, and in it each mobile phone number is marked as being associated with a

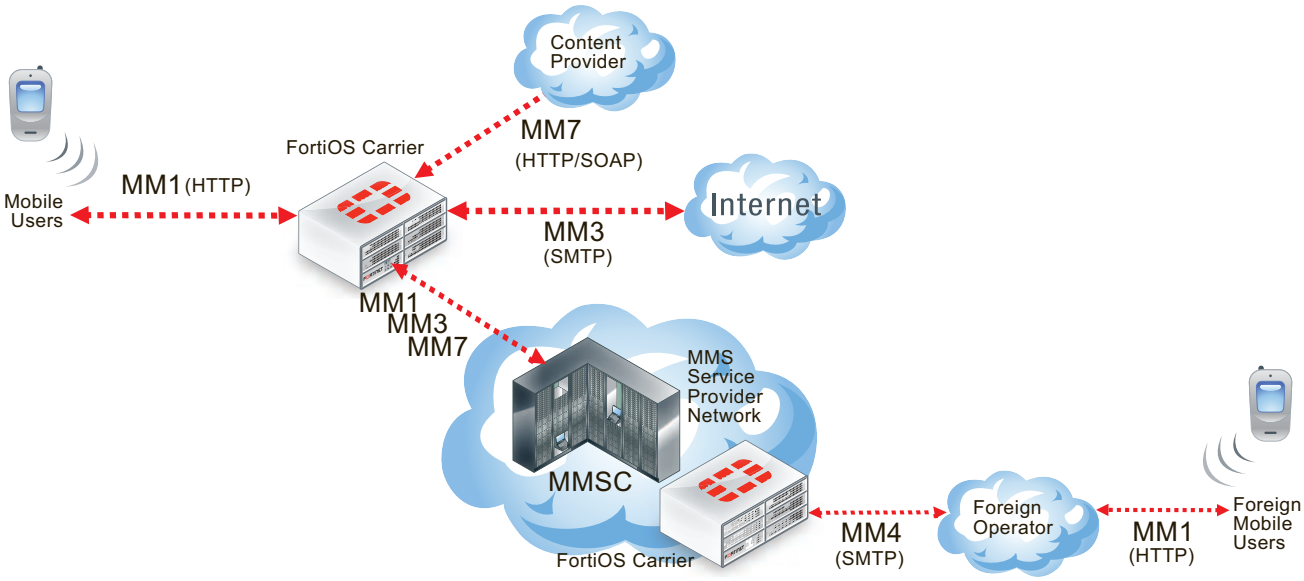
legacy handset or not. It can be a bit hit and miss since customers can change their handset at will and this database is not usually updated dynamically.

Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier endpoint filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

FortiOS Carrier MMS processing



FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

FortiOS Carrier and MMS content scanning

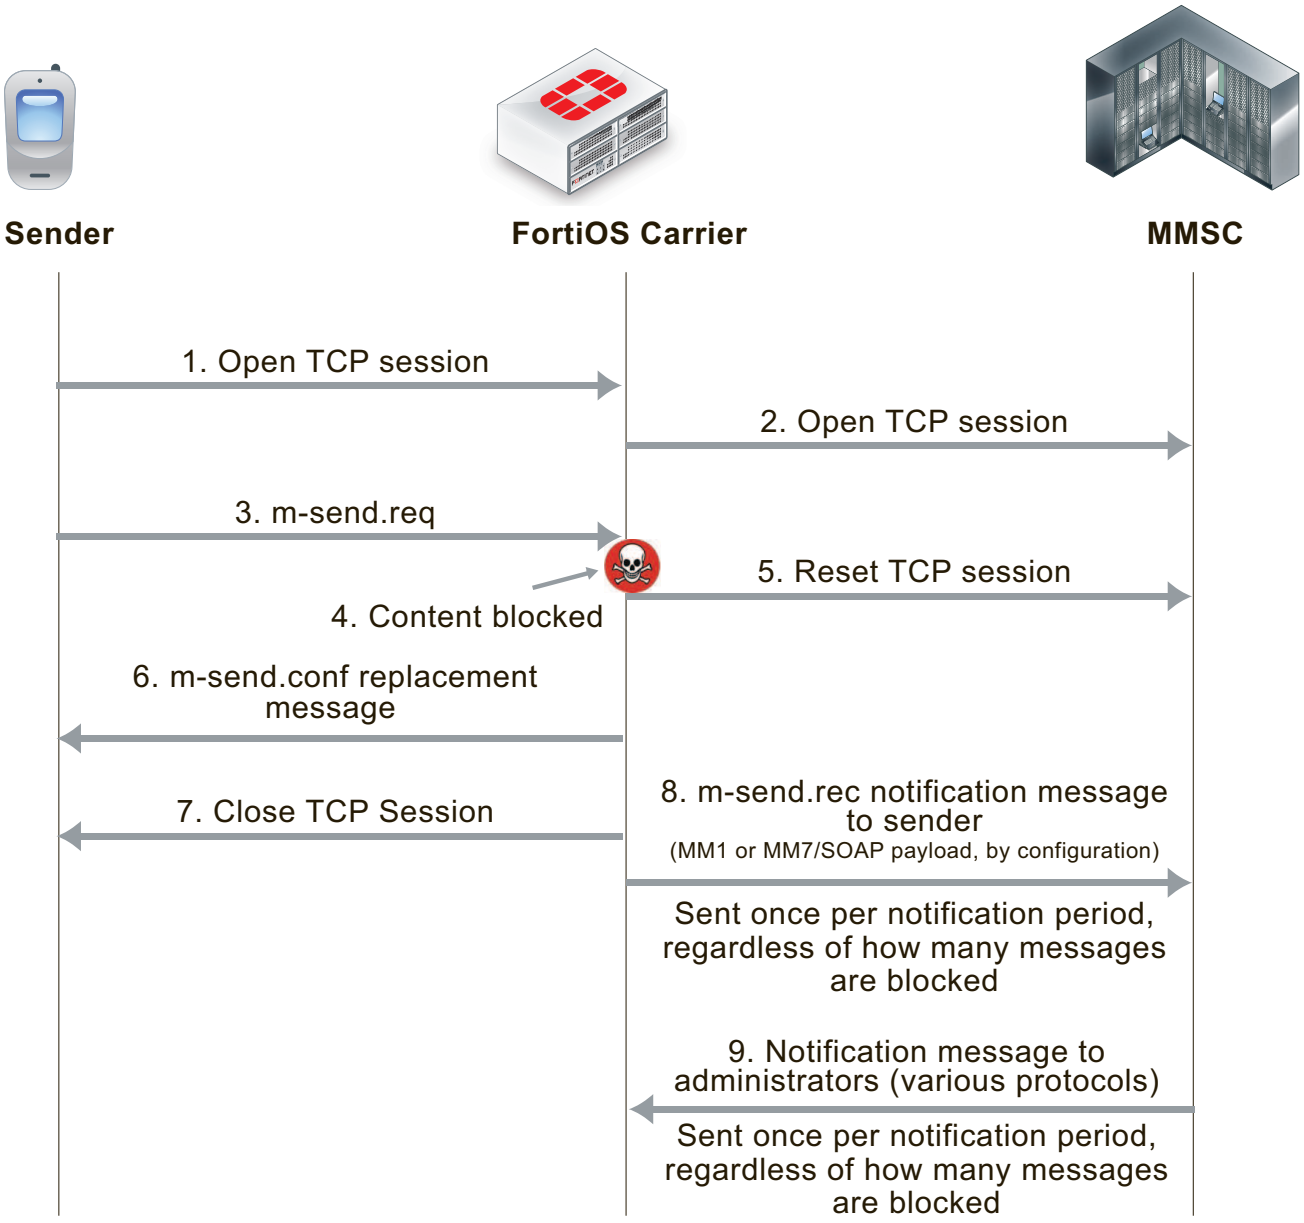
The following section applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier endpoint filtering, and MMS content checksum filtering.

MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found, see the figure below), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

MM1 MMS scanning of message sent by sender (blocking m.send.req messages)



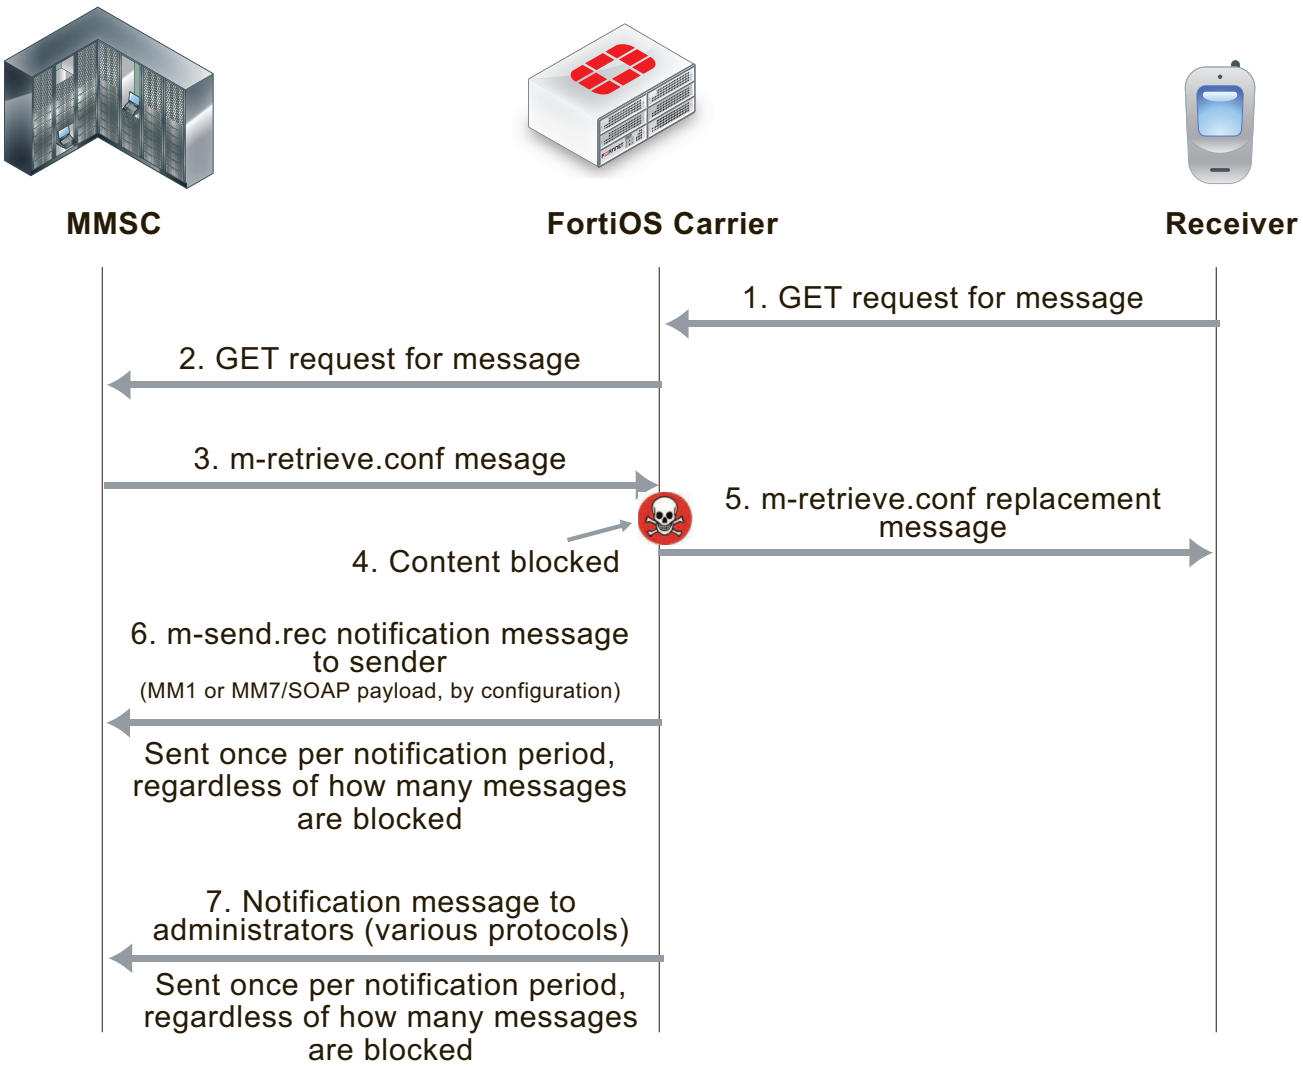
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

Filtering message retrieval

FortiOS Carrier intercepts the connection to the MMSC, and the m-retrieve.conf HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an m-retrieve.conf message from the associated replacement message and transmits this back to the client.

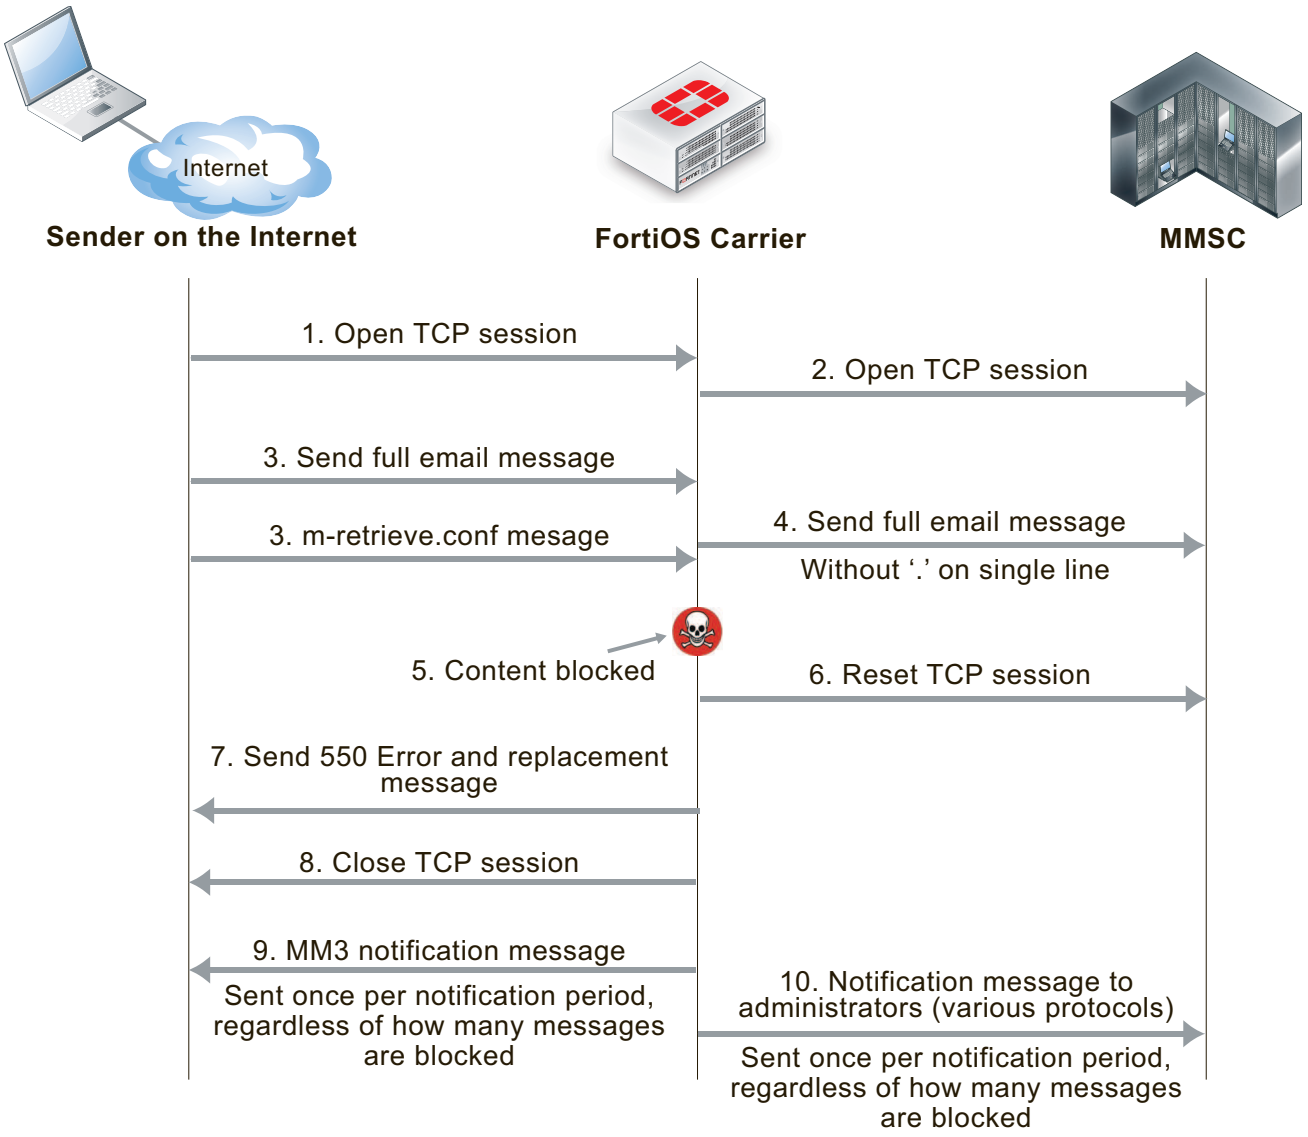
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)

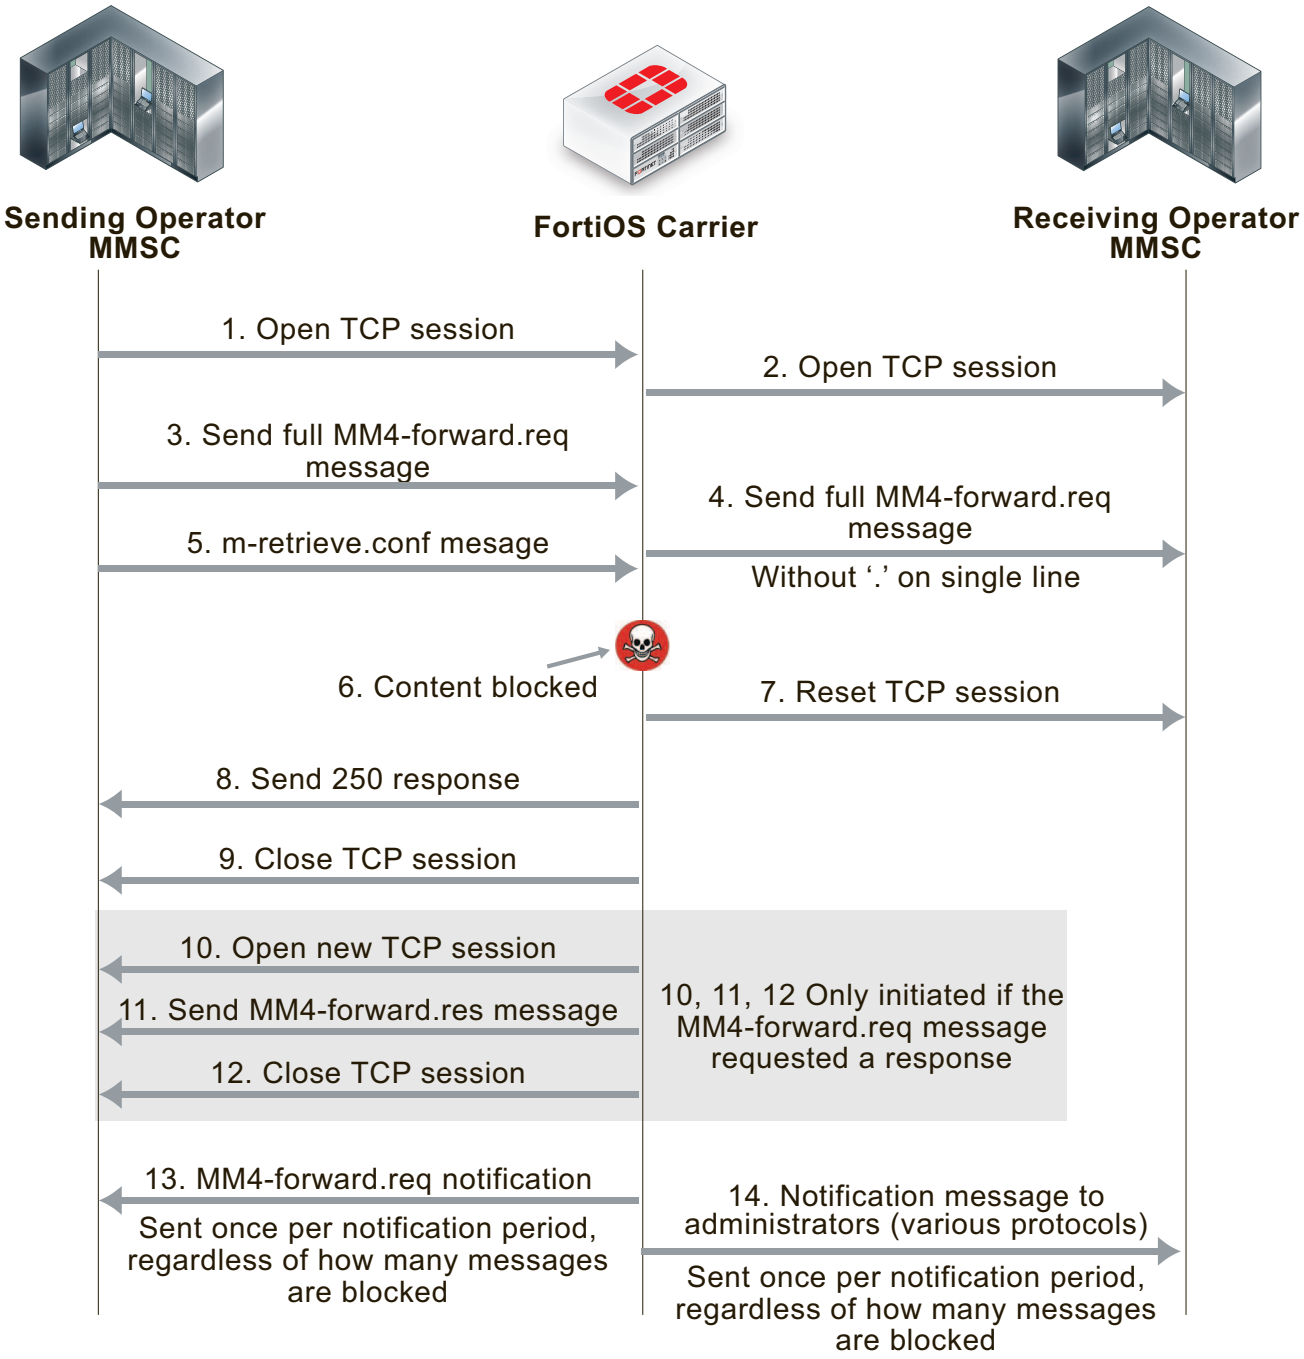


Filtering MM3 and MM4 messages works in an similar way to MM1 (see the figures below). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

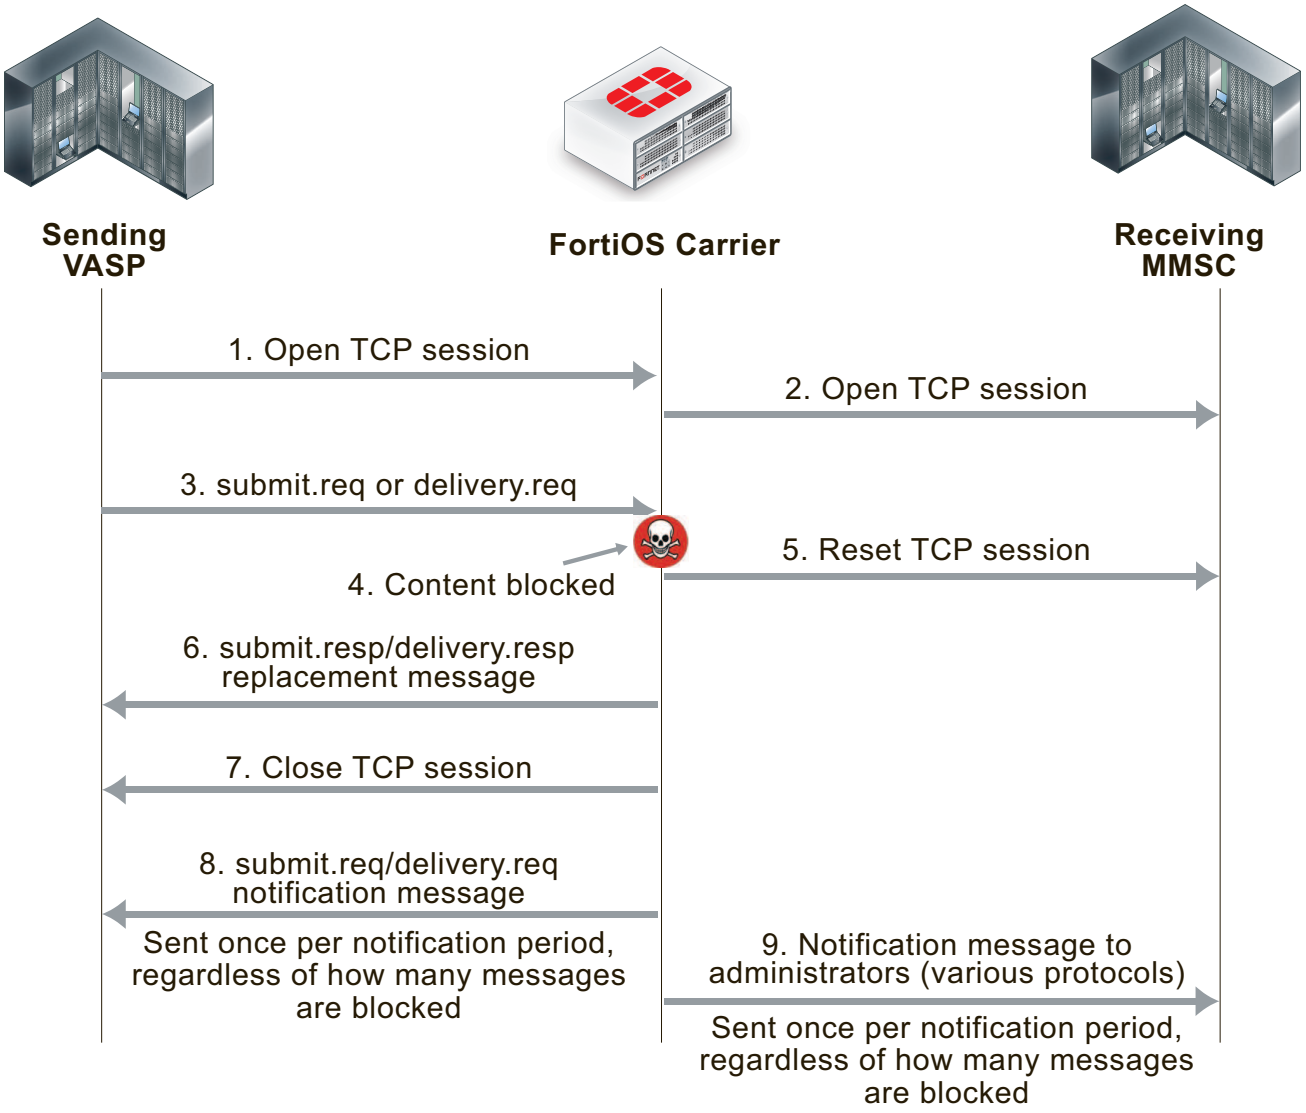
MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC



MM4 MMS scanning of messages sent between operator MMSCs



MM7 MMS scanning of messages sent between a VASP and an MMSC



FortiOS Carrier and MMS duplicate messages and message floods

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

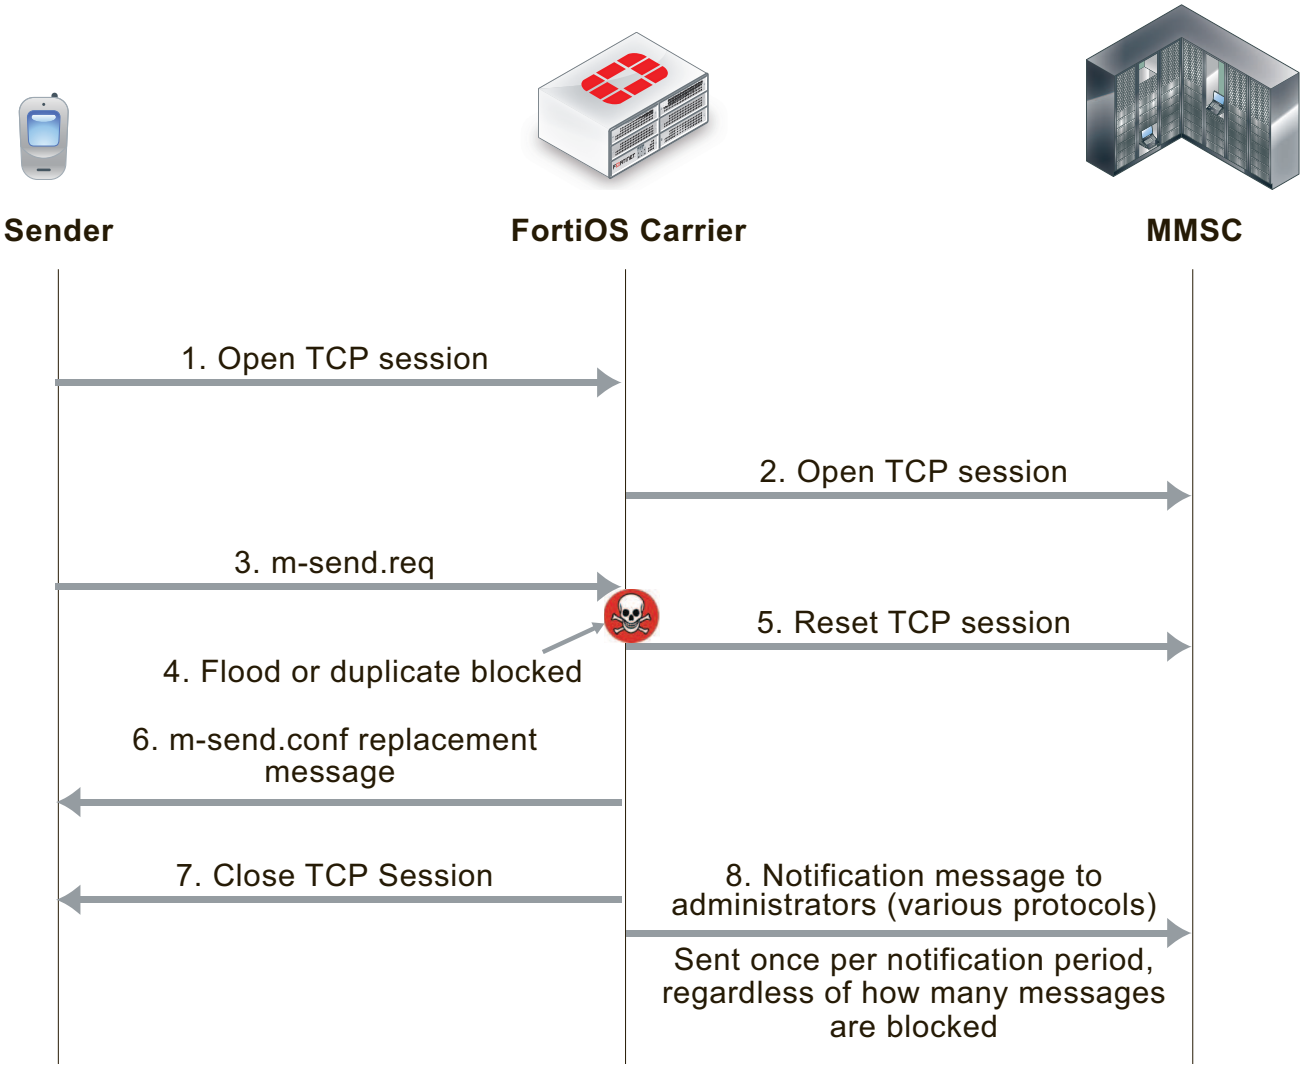
For message floods and duplicate messages, the sender does not receive notifications about floods or duplicate messages, as if the sender is an attacker they can gain useful information about flood and duplicate thresholds. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the

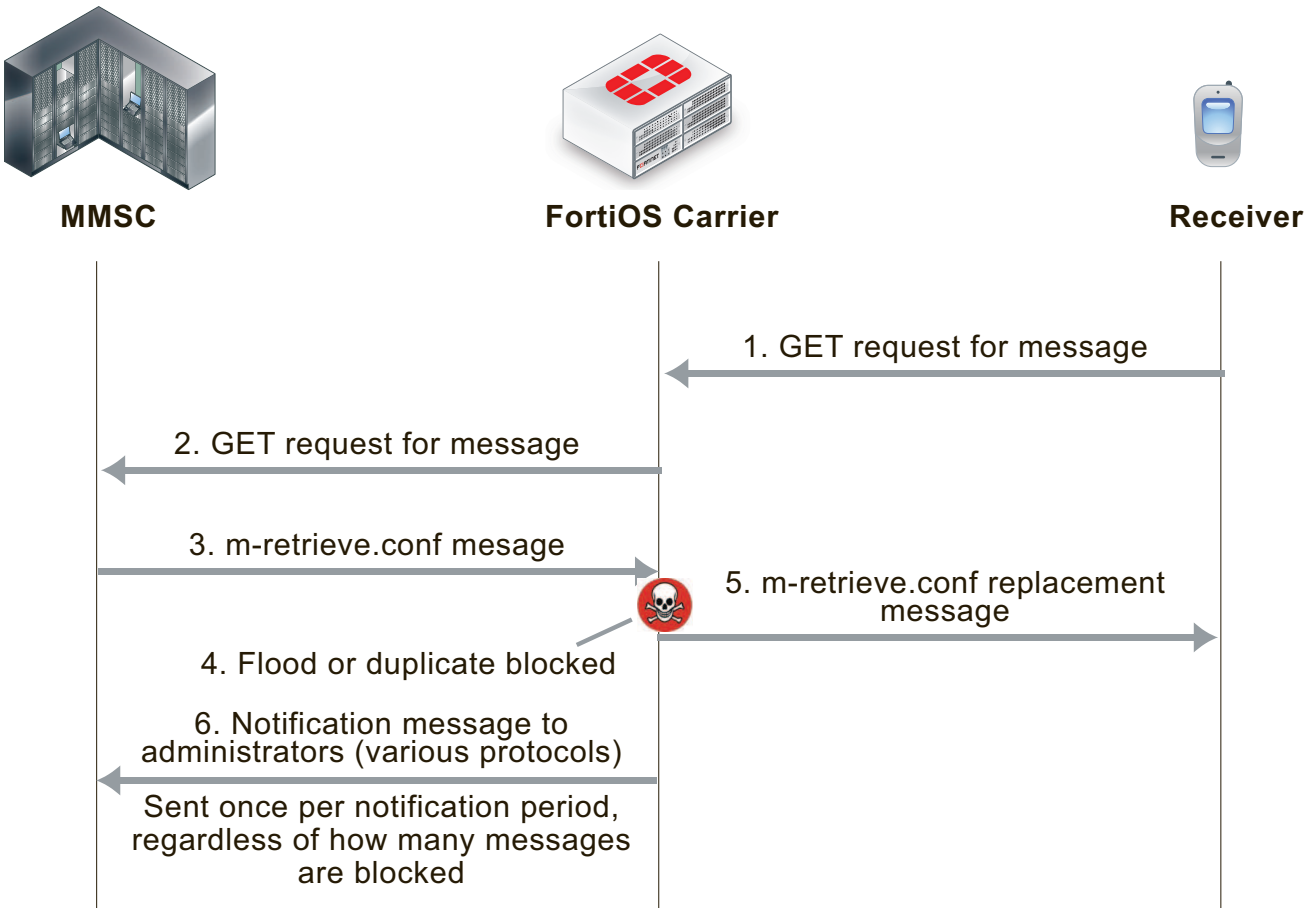
messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends m-send.conf or m-retrieve.conf messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

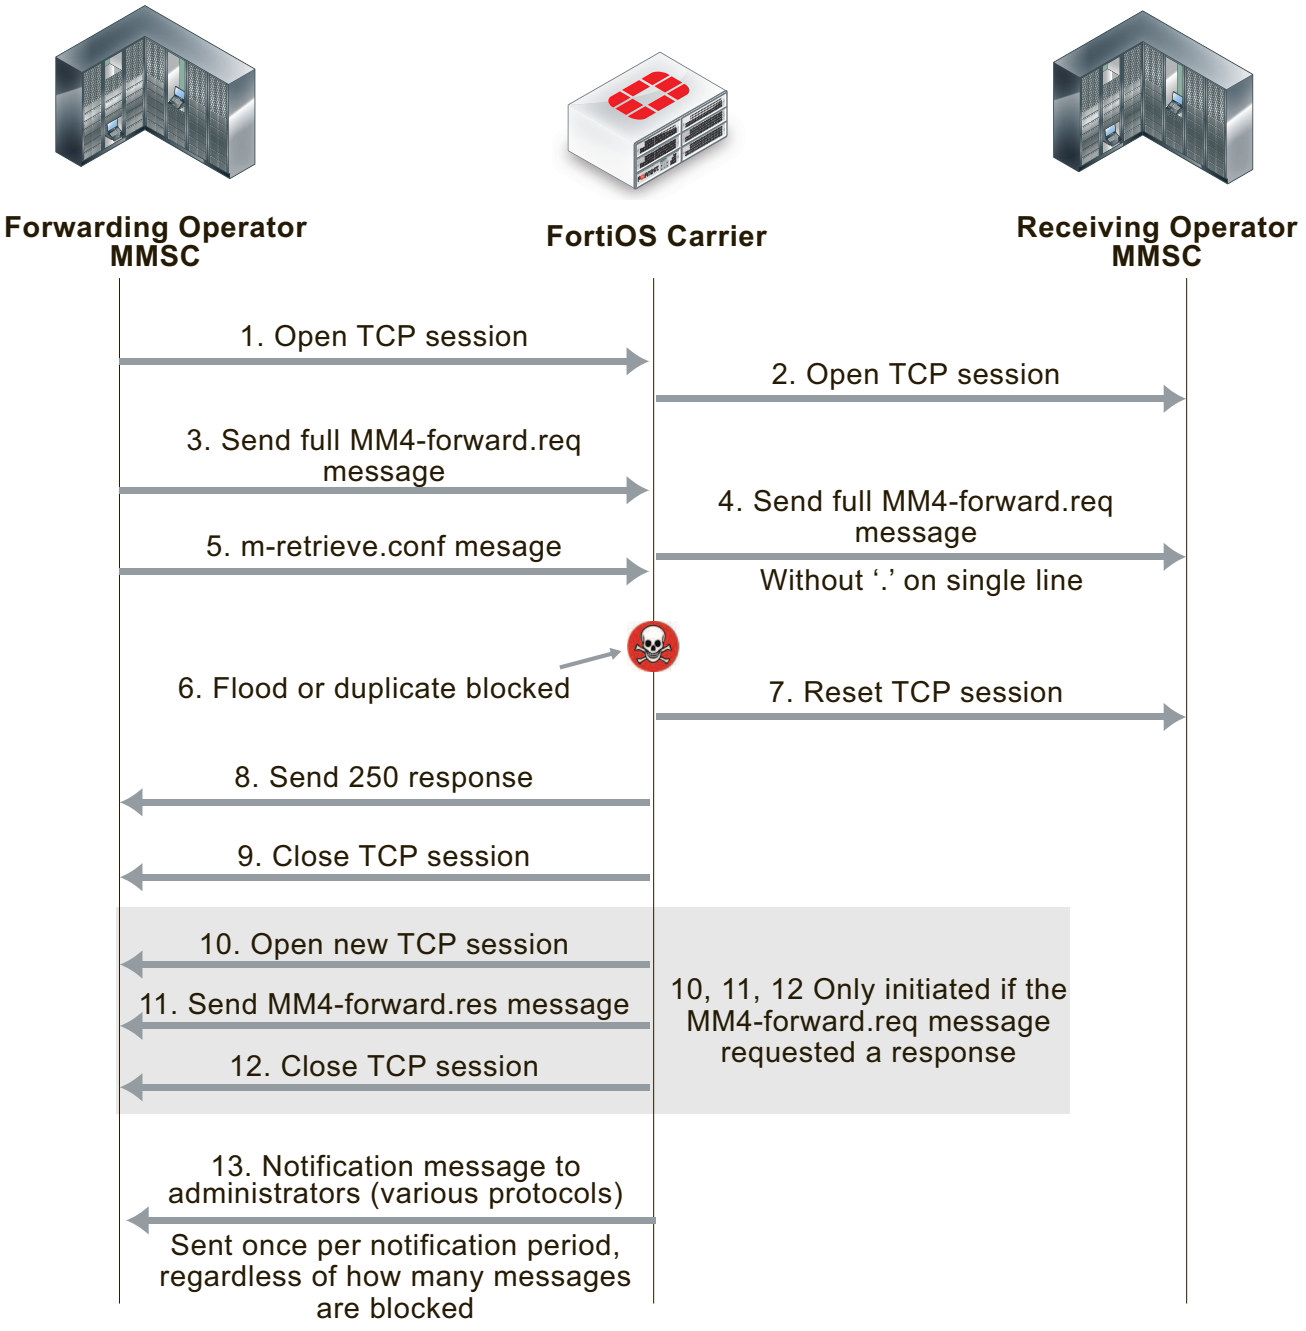
MM1 message flood and duplicate message blocking of sent messages



MM1 message flood and duplicate message blocking of received messages



MM4 message flood and duplicate message blocking



MMS protection profiles

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that

require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

Bypassing MMS protection profile filtering based on carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from MMS protection profile filtering. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier endpoints bypass MMS protection profile filtering. See Bypassing message flood protection based on user's carrier endpoints.

Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the Carrier security profile. The MMS protection profile then applies itself to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

To add an MMS protection profile to a security policy

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Select **Create New** to add an MMS protection profile.
3. Configure as needed, and save.
4. Go to **Policy & Objects > Policy > IPv4**.
5. Select **Create New** to add a security policy, or select an existing policy and **Edit** to add the MMS profile.
6. Configure the security policy as required.
7. Enable **MMS Profile**, and select the MMS profile to add to the security policy.
8. Select **OK**.

GTP basic concepts

GPRS currently supports data rates from 9.6kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone attempts to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The endpoint that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the endpoint either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see Tunnel Management Messages.

Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a downlink GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.

7. The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.
8. The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.
9. Now traffic can pass from the MS to the external network endpoint.

A GGSN creates a PDP context

1. The network receives an IP packet from an external network.
2. The GGSN checks if the PDP Context has already been created.
3. If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.
4. The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.
5. The SGSN sends to the MS a request to activate the indicated PDP context.
6. The PDP context activation procedure follows the one initiated by the MS. See "A Mobile Station creates a PDP context".
7. When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being overbilled for the extra usage. Anti-overbilling helps prevent this. See Configuring Anti-overbilling in FortiOS Carrier.

GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record, using the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet is preserved because the tunnel the handset has to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

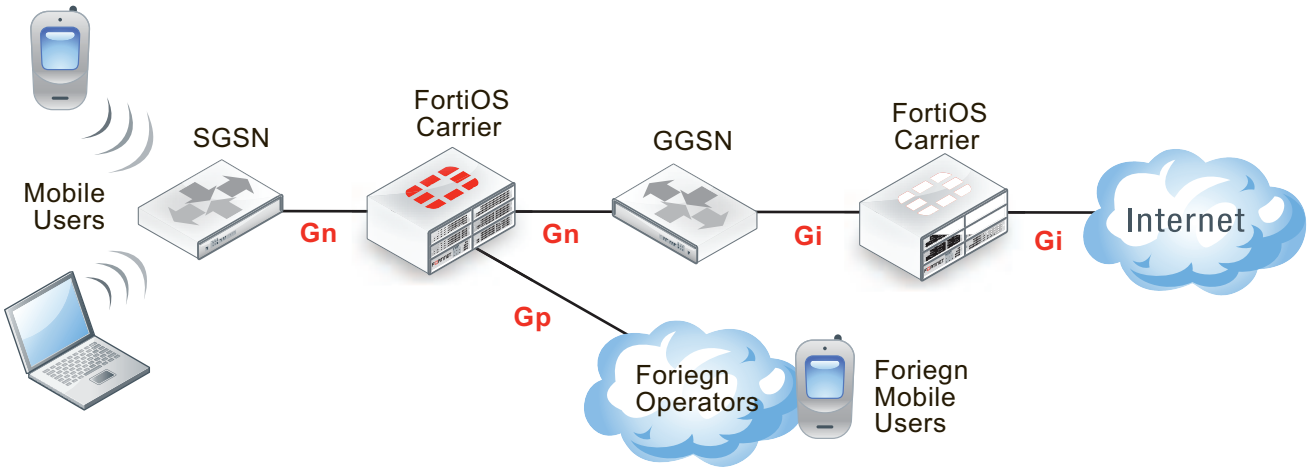
The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS).
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table.

Carrier network showing the interfaces used (GTPv1)



Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
SGSN (local)	MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	SGSN (local)	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a Carrier-enabled FortiGate unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their

network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

GTPv0

There have been three versions of GTP to date. The original version of GTP (version 0) has the following differences from version GTPv1.

- the tunnel identification is not random
- there are options for transporting X.25
- the fixed port number 3386 is used for all functions, not just charging
- optionally TCP is allowed as a transport instead of UDP
- not all message types are supported in version 0

GTPv1

On a GPRS network, Packet Data Protocol (PDP) context is a data structure used by both the Serving GPRS Support Node (SGSN) and the Gateway GPRS Support Node (GGSN). The PDP context contains the subscribers information including their access point, IP address, IMSI number, and their tunnel endpoint ID for each of the SGSN and GGSN.

The Serving GPRS Support Node (SGSN) is responsible for the delivery of data packets from and to the mobile stations within its geographical service area. Its tasks include packet routing and transfer, mobility management (attach/detach and location management), logical link management, and authentication and charging functions. The location register of the SGSN stores location information (e.g., current cell, current VLR) and user profiles (e.g., IMSI, address(es) used in the packet data network) of all GPRS users registered with this SGSN.

GTPv1-C

GTPv1-C refers to the control layer of the GPRS Transmission network. This part of the protocol deals with network related traffic.

FortiOS Carrier handles GTPv1-C in GTPv1 by using the Tunnel Endpoint IDentifier (TEID), IP address and a Network layer Service Access Point Identifier (NSAPI), sometimes called the application identifier, as an integer value that is part of the PDP context header information used to identify a unique PDP context in a mobile station, and SGSN.

For more information on GTPv1-C, see GTP-C messages.

GTPv1-U

GTPv1-U is defined in 3GPP TS 29.281 and refers to the user layer of the GPRS Tunneling network. This part of the protocol deals with user related traffic, user tunnels, and user administration issues.

A GTPv1-U tunnel is identified by a TEID, an IP address, and a UDP port number. This information uniquely identifies the limb of a GTPv1 PDP context. The IP address and the UDP port number define a UDP/IP path, a connectionless path between two endpoints (i.e. SGSN or GGSN). The TEID identifies the tunnel endpoint in the

receiving GTPv1-U protocol entity; it allows for the multiplexing and demultiplexing of GTP tunnels on a UDP/IP path between a given GSN-GSN pair. For more information on GTPv1-U, see GTP-U messages.

The GTP core network consists of one or more SGSNs and GGSNs.

GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the GGSN also forwards outgoing packets to the external PDN. the GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

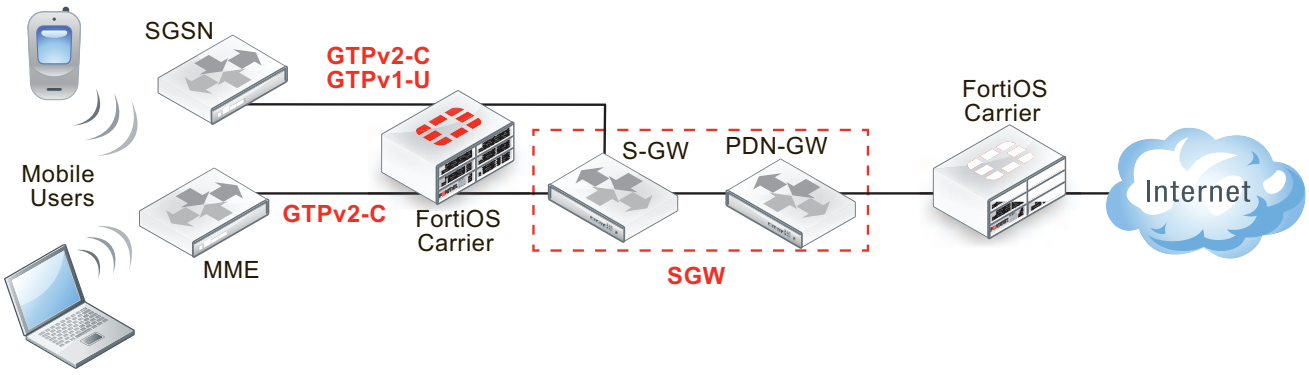
SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

GTPv2

GTPv2, defined in 3GPP TS 29.274, is dramatically differnet from GTPv1, defined in 3GPP TS 29.060. Where in GTPv1 the tunnel is between the SGSN and the GGSN, in GTPv2 The SGSN is between the MME and the LTE Serving Gateway (S-GW), beyond which is the PDN gateway (P-GW). Even tunnel management messages have changed significantly.

Network diagram for GTPv2



Device roles on a GTPv2 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	--
GTPv1 Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
GTPv2 Mobile Stations (MS)	Mobile Users, MME	???	IP, Frame Relay
SGSN (local)	GTPv1 MS, SGSN, S-GW	???	IP, Frame Relay, GTPv1, GTP'
S-GW	SGSN, MME, P-GW	???	IP, GTPv2, GTP'
P-GW	S-GW, Internet, other external services	???	IP, GTPv2

GTPv2-C

GTPv2-C is the control layer messaging for GTPv2. It is used by LTE mobile stations, SGSN units for backwards compatibility, and SGWs that are the gateway to other networks. The messaging is very different from GTPv1. GTPv2-C is required to communicate with the Mobility Management Entity (MME) to create, change and delete EPS bearers when handover events happen, and to create Forwarding tunnels. The protocol is also used to communicate with the Serving Gateway (SGW) which has the S-GW and PDN-GW interfaces, and the Serving GPRS Support Node (SGSN).

MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP' is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

GTP' (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP' (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP' transports user records from many individual network elements, such as the GGSNs, to a centralised computer which then delivers the charging data

more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP' is used by the Ga and Gz interfaces to transfer billing information. GTP' uses registered UDP/TCP port 3386. GTP' defines a different header, additional messages, field values, as well as a synchronisation protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP', see GTP-U and Charging Management Messages.

GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. There interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network is has a name in the format of `Gx` where `x` is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices.

The Carrier-enabled FortiGate unit only provides protection on the Gn, Gp, and Gi interfaces.

GPRS network interfaces, their roles, and billing

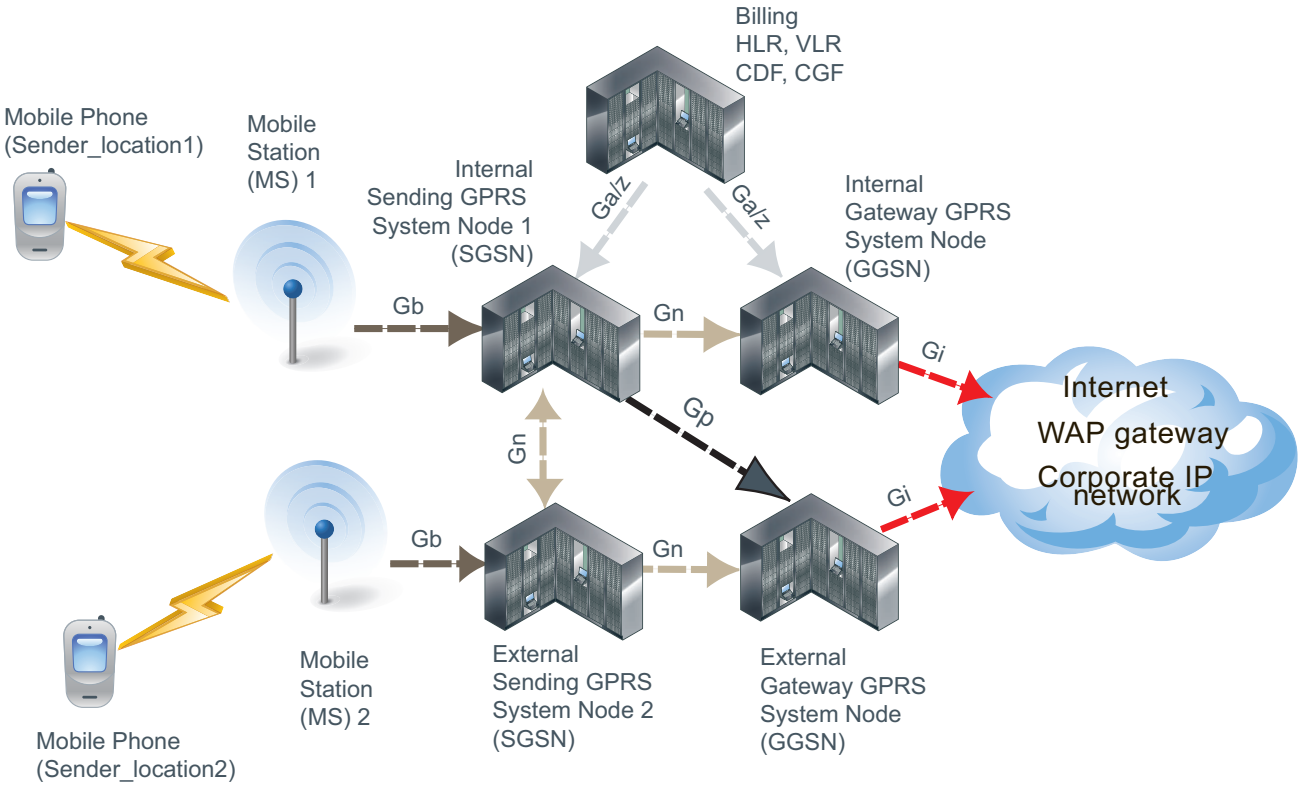
Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
Ga	CDR and GSN (SGSNs and GGSNs)	GTP' - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)
Gb	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
Gi	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See Anti-overbilling with FortiOS Carrier.
Gn	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
Gp	Internal SGSN and external GGSNs	GTP	
Gz	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP'	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

Packet flow through the GPRS network

To better understand the GPRS network, we will follow the path data takes for a normal connection. For this example a call placed from a mobile phone involves accessing services on the Internet.

Sample GPRS network topology



1. A mobile phone places a call using a mobile station (MS). This connection between the mobile phone and the MS is a radio connection using one of the radio access technologies. See Radio Access Technology (RAT) type.
2. The MS connects to a GPRS System Node (GSN) specifically a Sending GSN. This connection uses the Gb interface and typically uses IP address or Frame Relay.
3. The SGSN checks the mobile phone information located in the home location register (HLR) or visitor location register (VLR) to ensure there is subscriber information for that phone. If this mobile phone is from another network, the SGSN uses the VLR and updates its home carrier's information with its current location and information. This connection involves the Ga or Gz interfaces, and uses the GTP' protocol for communication.
4. The SGSN checks to make sure the phone did not transfer this connection from a different MS. If it did, the connection has already been established (along with the billing) and is handed off to this SGSN. If the call is being handed over from another SGSN, it will use the Gn interface between the two SGSNs.
5. The SGSN sends GTP messages to the local external Gateway GSN (GGSN) to create a GTP tunnel for this PDP context to access the Internet. It is possible that a remote GGSN has access to a service, such as a WAP gateway, that the local GGSN is missing. In this situation, the local SGSN uses the Gp interface to connect to the remote GGSN. Both the Gn and Gp interfaces use GTP.
6. The both the local and remote GGSNs connect to external services outside the GPRS network. These services can include a WAP gateway, a corporate IP network directly connected to the GPRS network, or the Internet. The connection from the GGSN to the external services uses the Gi interface.

SCTP

As of FortiOS version 5.0, the FortiGate natively handles SCTP (Stream Control Transport Protocol) traffic, as an alternative to TCP and UDP for use in Carrier networks. The FortiGate handles SCTP as if it would any other traffic.

Overview

SCTP is a connection-oriented transport protocol that overcomes some of the limitations of both TCP and UDP that prevent reliable transfer of data over IP-based networks (such as those used by telephony systems and carrier networks). The 'Stream' in SCTP refers to the sequence of user messages or packets that are considered at the same time to be individual objects and also treated as a whole by networked systems. SCTP is less vulnerable to congestion and flooding due to more advanced error handling and flood protection built into the protocol.

SCTP features as compared to TCP and UDP

Feature	SCTP	TCP	UDP
State required at each endpoint	yes	yes	no
Reliable data transfer	yes	yes	no
Congestion control and avoidance	yes	yes	no
Message boundary conservation	yes	no	yes
Path MTU discovery and message fragmentation	yes	yes	no
Message bundling	yes	yes	no
Multi-homed hosts support	yes	no	no
Multi-stream support	yes	no	no
Unordered data delivery	yes	no	yes
Security cookie against SYN flood attack	yes	no	no
Built-in heartbeat (reachability check)	yes	no	N/A

All of these features are built into the design of the Protocol, and the structure of SCTP packets and networks. The FortiGate unit interprets the traffic and provides the necessary support for maintenance and verification features, but the features are not FortiGate specific. These features are documented in greater detail below.

State required at each endpoint

Constant back and forth acknowledgement and content verification messages are sent between all SCTP peer endpoints, and all endpoints' state machine actions must be synchronized for traffic to flow.

Reliable data transfer

SCTP places data and control information (eg. source, destination, verification) into separate messages, both sharing the same header in the same SCTP packet. This allows for constant verification of the contained data at both ends and along the path, preventing data loss or fragmentation. As well, data is not sent in an interruptible stream as in TCP.

Congestion control and avoidance

Built-in, constantly updating path detection and monitoring automatically redirect packets along alternate paths in case of traffic congestion or inaccessible destinations. For deliberate/malicious congestion control, see the below section on Security cookie against SYN flood attack.

Message boundary conservation

SCTP is designed in such a way that no matter how messages are divided, redirected, or fragmented, the message boundaries will be maintained within the packets, and all messages cannot be appended without tripping verification mechanisms.

Path MTU discovery and message fragmentation

SCTP is capable of Path Maximum Transmission Unit discovery, as outlined in RFC4821. Two specific alterations have been made to how SCTP handles MTU. First, that endpoints will have separate MTU estimates for each possible multi-homed endpoint. Second, that bundled message fragments (as explained below) will be directed based on MTU calculations, so that retransmissions (if necessary) will be sent without delay to alternate addresses.

Message bundling

SCTP is a message-oriented protocol, which means that despite being a streaming data protocol, it transports a sequence of specific messages, rather than transporting a stream of bytes (like TCP). Since some data transmissions are small enough to not require a complete message's worth of content, so multiple pieces of content will be transmitted simultaneously within the messages.

Multi-homed hosts support

SCTP supports multi-homing, which is a network structure in which one or multiple sources/destinations has more than one IP address. SCTP can adapt to multi-homing scenarios and redirect traffic to alternate IP addresses in case of failure.

Multi-stream support

Due to the message bundling feature allowing for multiple pieces of content to be sent in messages at once, SCTP can 'multi-stream' content, by deliberately dividing it among messages at a fixed rate, so that multiple types of content (eg. both images and text) can be loaded at once, at the same pace.

Unordered data delivery

With control messages in every packet to provide verification of any packet's data and its place in the stream, the data being transmitted can actually arrive in any order, and verify that all has arrived or that some is missing.

Security cookie against SYN flood attack

Since every packet contains verification of its place in the stream, it makes it easy for the protocol to detect when redundant, corrupted or malicious packets flood the path, and they are automatically dropped when necessary.

Built-in heartbeat (reachability check)

Endpoints automatically send specific control chunks among the other SCTP packet information to peer endpoints, to determine the reachability of the destination. Hearthbeat acknowledgement packets are returned if the destination is available.

SCTP Firewall

FortiGate stateful firewalls will protect and inspect SCTP traffic, according to RFC4960. SCTP over IPsec VPN is also supported. The FortiGate device is inserted as a router between SCTP endpoints. It checks SCTP Syntax for the following information:

- Source and destination port
- Verification Tag
- Chunk type, chunk flags, chunk length
- Sequence of chunk types
- Associations

The firewall also oversees and maintains several SCTP security mechanisms:

- SCTP four-way handshake
- SCTP heartbeat
- NAT over SCTP

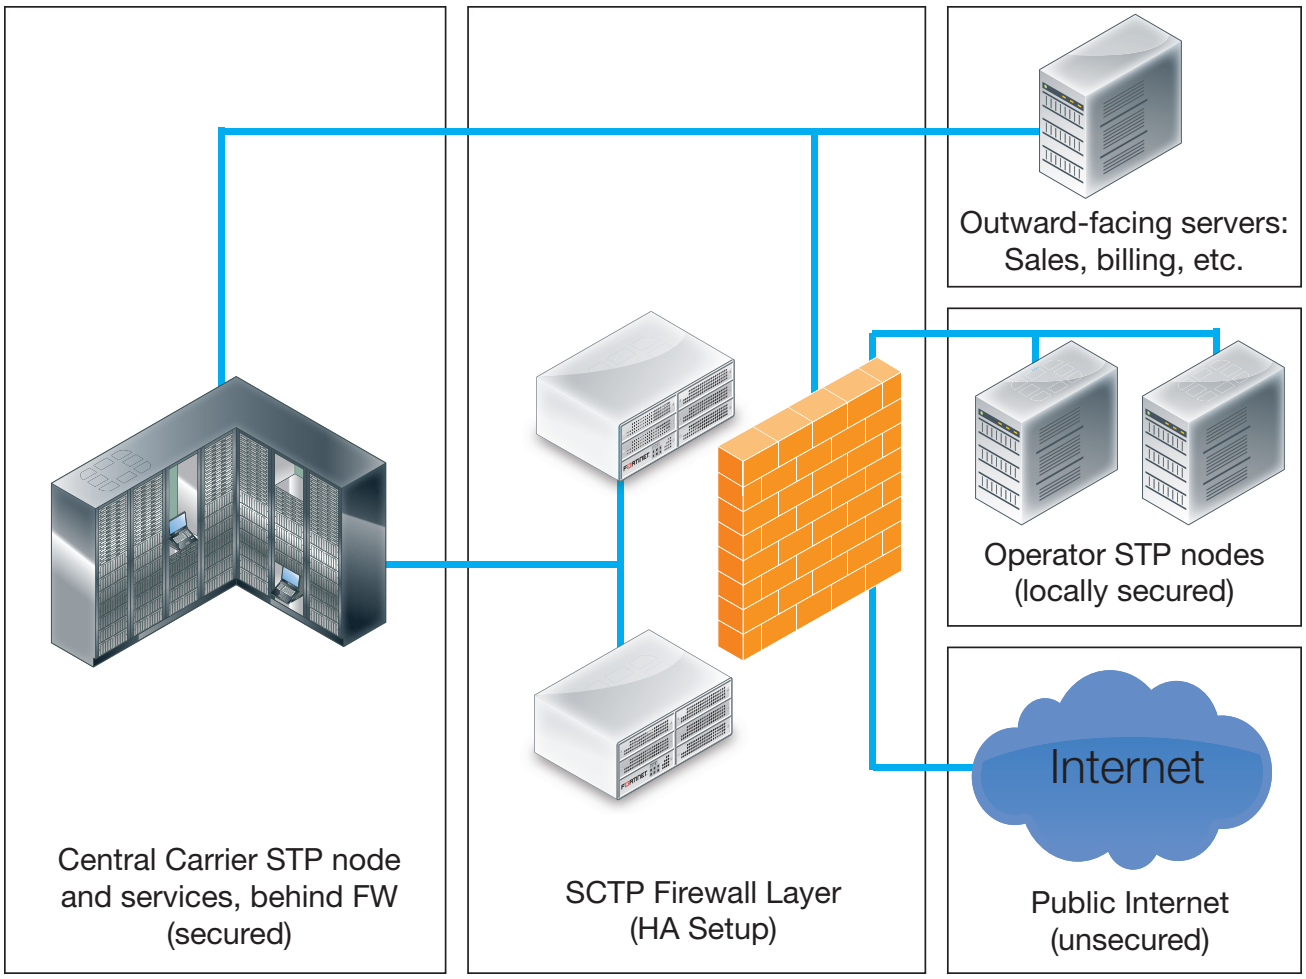
The firewall has IPS DoS protection against known threats to SCTP traffic, including INIT/ACK flood attacks, and SCTP fuzzing.

SCTP example scenario

An ideal SCTP configuration for a Carrier serving multiple operators/service providers involves a unified Firewall, securing all incoming and outgoing traffic over the Carrier network, whether it be standard web traffic, GTP or other carrier traffic, or corporate traffic for the Carrier company.

One best practice method to provide a unified firewall with built-in redundancy is to make use of multiple FortiGate units, connected in a High Availability cluster. Also, there are additional methods that can be applied to ease the complexity of managing multiple services, functions, and traffic types across multiple devices.

Sample SCTP Network Topology

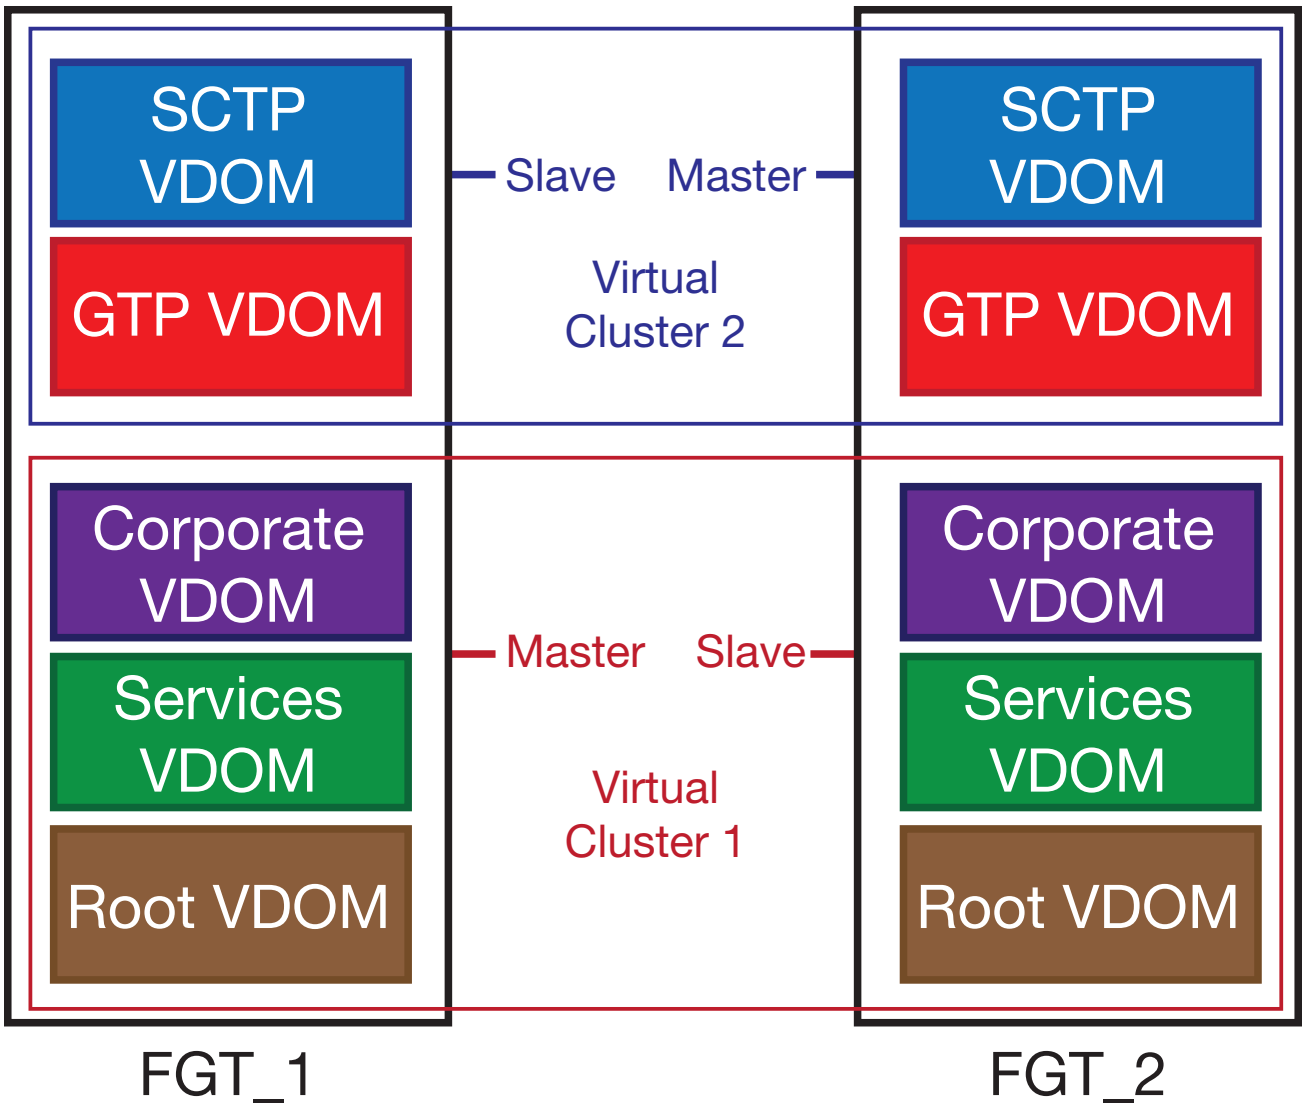


In this example, the firewall layer is configured with two FortiGate devices to act as an HA cluster, providing automatic load balancing and failover detection for the main firewall.

The two devices together make up the firewall, through which all traffic passes. Virtual Domains are created within the FortiGate units, distributing services and traffic into individual VDOMs, allowing them to be monitored and secured individually, to help mitigate possible threats to Carrier networks that target specific services. Individual departments or administrators can manage specific VDOMs, or the FortiGates can be collectively managed centrally by network administrators.

The VDOMs are distributed as shown below:

VDOM distribution between SCTP Firewall Layer FortiGate units



One FortiGate handles basic FortiGate services and non-Carrier traffic. Configuring virtual clustering across the two FortiGates allows one to mirror its VDOMs across to the other unit.

The second FortiGate can then primarily provide Carrier-specific services and handle SCTP, Gi and GTP traffic, using the first FortiGate as the slave unit in a second virtual cluster.

Carrier web-based manager settings

The Carrier menu provides settings for configuring FortiOS Carrier features within the Security Profiles menu. These features include MMS and GTP profiles.

In **Security Profiles > Carrier**, you can configure profiles and settings for MMS and GTP. In the Carrier menu, you can configure an MMS profile and then apply it to a security policy. You can also configure GTP profiles and apply those to security policies as well.

This topic includes the following:

MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the Authentication guide.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning
- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

MMS profile configuration settings

The following are MMS profile configuration settings in **Security Profiles > Carrier > MMS Profile**.

MMS Profile page Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
Create New	Creates a new MMS profile. When you select **Create New**, you are automatically redirected to the New MMS Profile page.
Edit	Modifies settings within an MMS profile. When you select **Edit**, you are automatically redirected to the Edit MMS Profile.
Delete	Removes an MMS profile from the list on the MMS Profile page. To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select **Delete**. To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select **Delete**.
Name	The name of the MMS profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

New MMS Profile page	
Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.	
Profile Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
MMS Scanning	Configure MMS Scanning options.
MMS Bulk Email Filtering Detection	Configure MMS Bulk Email options.
MMS Address Translation	Configure MMS Address Translation options.
MMS Notifications	Configure MMS Notification options.
DLP Archive	Configure DLP archive option.
Logging	Configure logging options.

MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier endpoint blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in **Security Profiles > Carrier > MMS Profile** or edit an existing one. You must expand MMS Scanning to access the following options.

MMS Scanning section of the New MMS Profile page	
Monitor Only	Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users. **Tip:** Select **Remove Blocked** if you want the unit to actually remove content intercepted by MMS scanning options.
Virus Scan	Select to scan attachments in MMS traffic for viruses. Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning. MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.
Scan MM1 message retrieval	Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.
Quarantine	Select to quarantine the selected MMS traffic
Remove Blocked	Select to remove blocked content from each protocol and replace it with the replacement message. Select **Constant** if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message. **Tip:** If you only want to monitor blocked content, select **Monitor Only**.
Content Filter	Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list. For information about adding a web content filter list, see the FortiGate CLI Reference.
Carrier Endpoint Block	Select to add **Carrier Endpoint Filtering** in this MMS profile. Select the carrier endpoint filter list to apply it to the profile.
MMS Content Checksum	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.

MMS Scanning section of the New MMS Profile page	
Pass Fragmented Messages	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
Comfort Clients	Select client comforting for MM1 and MM7 sessions. Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.
Comfort Servers	Select server comforting for each protocol. Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.
Interval (1-900 seconds)	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
Amount (1-10240 bytes)	The number of bytes sent by client or server comforting at each interval.
Oversized MMS Message	Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol. The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.
Threshold (1KB - 800 MB)	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the ***Oversized MMS Message*** setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

MMS bulk email filtering options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the **Duplicate Message Action** for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

MMS Bulk Email Filtering Detection

This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.

Message Flood

The message flood settings for each flood threshold. Expand each to configure settings for a threshold.

Flood Threshold 1	Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
Enable	Select to apply Flood Threshold 1 to the MSISDN exception.
Message Flood Window	Enter the period of time during which a message flood will be detected if the **Message Flood Limit** is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
Message Flood Limit	Enter the number of messages which signifies a message flood if exceeded within the **Message Flood Window**.
Message Flood Block Time	Enter the amount of time during which the unit performs the **Message Flood Action** after a message flood is detected.
Message Flood Action	Select one or more actions that the unit is to perform when a message flood is detected.
Flood Threshold 2	Expand to configure settings for Flood Threshold 2 or 3 respectively.
Flood Threshold 3	

Duplicate Message

The duplicate message threshold settings. Expand each to configure settings for a threshold.

MM1 Retrieve Duplicate Enable	Select to scan MM1 `mm1-retr` messages for duplicates. By default, `mm1-retr` messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
Enable	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
Duplicate Message Window	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
Duplicate Message Limit	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.

Duplicate Message Block Time	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
Duplicate Message Action	Select one or more actions that the unit is to perform when excessive message duplication is detected.
Duplicate Threshold 2	Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
Duplicate Threshold 3	

Recipient MSISDN

The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select **Create New**, you are automatically redirected to the New MSISDN page.

You need to save the profile before you can add MSISDNs.

Recipient MSISDN	The recipient MSISDN.
Flood Threshold 1	Check to enable Flood Threshold 1 settings for this MSISDN.
Flood Threshold 2	ICheck to enable Flood Threshold 2 settings for this MSISDN..
Flood Threshold 3	ICheck to enable Flood Threshold 3 settings for this MSISDN..
Duplicate Threshold 1	Check to enable Duplicate Threshold 1 settings for this MSISDN..
Duplicate Threshold 2	Check to enable Duplicate Threshold 2 settings for this MSISDN..
Duplicate Threshold 3	Check to enable Duplicate Threshold 3 settings for this MSISDN..
Edit	Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select **Edit**, you are automatically redirected to the New MSISDN page.
Delete	Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.

New MSISDN page

Create New	Creates a new Recipient MSISDN. When you select **Create New**, you are automatically redirected to the New MSISDN page.
Recipient MSISDN	Enter a name for the recipient MSISDN.
Flood Threshold 1	Select to apply Flood Threshold 1 to the MSISDN exception.
Flood Threshold 2	Select to apply Flood Threshold 2 to the MSISDN exception.

Flood Threshold 3	Select to apply Flood Threshold 3 to the MSISDN exception.
Duplicate Threshold 1	Select to apply Duplicate Threshold 1 to the MSISDN exception.
Duplicate Threshold 2	Select to apply Duplicate Threshold 2 to the MSISDN exception.
Duplicate Threshold 3	Select to apply Duplicate Threshold 3 to the MSISDN exception.

MMS Address Translation options

The sender’s carrier endpoint is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the **From** field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the **To** address in the message. If this header field is not present the content of the **To** header field is used instead.

Alternatively, the unit can extract the sender’s address from a cookie.

You can configure MMS address translation to extract the sender’s carrier endpoint so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier endpoints from HTTP header fields or from cookies. You can also configure MMS address translation to add an endpoint prefix to the extracted carrier endpoints. For more information, see Dynamic Profiles and Endpoints in the Authentication guide.

MMS Address Translation	
Sender Address Source	Select to extract the sender's address from the **HTTP Header Field** or a **Cookie**. You must also specify the identifier that contains the carrier endpoint.

Sender Address Identifier	Enter the sender address identifier that includes the carrier endpoint. The default identifier is `x-up-calling-line-id`.
	
	If the **Sender Address Source** is **HTTP Header Field**, the address and its identifier in the HTTP request header takes the format:
	
	`<Sender Address Identifier>: <MSISDN_value>`
	
	Where the `<MSISDN_value>` is the carrier endpoint. For example, the HTTP header might contain:
	
	`x-up-calling-line-id: 6044301297`
	
	where `x-up-calling-line-id` would be the Sender Address Identifier.
	
	If the **Sender Address Source** is Cookie, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:
	
	`Cookie: id=<cookie-id>;`
	
	`<Sender Address Identifier>=<MSISDN Value>`
	
	For example, the HTTP request headers might contain:
	
	`Cookie: id=0123jf!a;x-up-calling-line-id=6044301297`
	
	where `x-up-calling-line-id` would be the **Sender Address Identifier**.

Convert Sender Address From / To HEX	Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.
Add Carrier Endpoint Prefix for Logging / Notification	Select the following to enable adding endpoint prefixes for logging and notification.
Enable	Select to enable adding the country code to the extracted carrier endpoint, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.

MMS Address Translation	
Prefix	Enter a carrier endpoint prefix to be added to all carrier endpoints. Use the prefix to add extra information to the carrier endpoint in the log entry.
Minimum Length	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (0), length is not limited.
Maximum Length	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (0), length is not limited.

MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more **Notification Types** or you can add an **Antivirus Notification List** to enable sending notifications,.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

MMS Notification	
Antivirus Notification List	Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select **Disabled** if you do not want to use a notification list. Instead of selecting a notification list you can configure the **Virus Scan Notification Type** to send notifications for all viruses.
Message Protocol	In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select. If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.
Message Type	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ
Detect Server Details	Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually. You cannot select **Detect Server Details** if you are sending notification messages using a different message protocol. If you select **Detect Server Details**, you cannot change the **Port** where the notification is being sent.
Hostname	Enter the FQDN or the IP address of the server where the notifications will be sent.
URL	Enter the URL of the server. For example if the notificaiton is going to www.example.com/home/alerts , the URL is /home/alerts. This option is available only when **Message Protocol** is **mm1** or **mm7**.
Port	Enter the port number of the server. You cannot change the ***Port*** if ***Detect Server Details*** is enabled.

MMS Notification	
Username	Enter the user name required for sending messages using this server (optional). This option is available only when **Message Protocol** is **mm7**.
Password	Enter the password required for sending messages using this server (optional). This option is available only when **Message Protocol** is **mm7**.
VASP ID	Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP). This option is available only when **Message Protocol** is **mm7**.
VAS ID	Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax. This option is available only when **Message Protocol** is **mm7**.
All Notification Types	In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals. Alternatively, expand **All Notification Types**, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals. Not all event types are available for all MMS protocols.
Content Filter	In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.
File Block	In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.
Carrier Endpoint Block	In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.
Flood	In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.

MMS Notification	
Duplicate	In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.
MMS Content Checksum	In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.
Virus Scan	In each column, select to notify when the content within an MMS message is scanned for viruses.
Notifications Per Second Limit	For each MMS protocol, enter the number of notifications to send per second. If you enter zero (0), the notification rate is not limited.
Day of Week	For each MMS protocol, select the days of the week the unit is allowed to send notifications.
Window Start Time	For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.
Window Duration	For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day. When configured, notification outside this window will not be sent

DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

DLP Archive	
Display DLP meta-information on the system dashboard	Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.
Archive to FortiAnalyzer/FortiGuard	Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None. **None —** Do not send content archives. **Summary —** Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result. **Full —** Send content archive both metadata and copies of files or messages. In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol. This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.

Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the FortiOS Handbook Logging and Reporting guide.

Logging	
MMS-Antivirus	If antivirus settings are enabled for this MMS profile, select the following options to record **Antivirus Log** messages.
Viruses	Record a log message when this MMS profile detects a virus.
Blocked Files	Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.
Intercepted Files	Record a log message when this MMS profile intercepts a file.
Oversized Files/E-mails	Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.
MMS Scanning	If MMS scanning settings are enabled for this MMS profile, select the following options to record **Email Filter Log** messages.
Notification Messages	Select to log the number of MMS notification messages sent.
Bulk Messages	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile.
Carrier Endpoint Filter Block	Select to log MMS carrier endpoint filter events, such as MSISDN filtering.
MMS Content Checksum	Select to log MMS content checksum activity.
Content Block	Select to log content blocking events.

MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in **Security Profiles > Carrier > MMS Content Checksum** using the following table.

MMS Content Checksum Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.	
Create New	Creates a new MMS content checksum list. When you select **Create New**, you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
Edit	Modifies settings to a MMS content checksum. When you select **Edit**, you are automatically redirected to the MMS Content Checksum Settings page.
Delete	Removes an MMS content checksum from the page. To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select **Delete**. To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select **Delete**.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in the content checksum list.
MMS Profiles	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
Comments	A description given to the MMS content checksum.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > AntiVirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

Notification list configuration settings

The following are notification list configuration settings in **Security Profiles > Carrier > Notification List**.

Notification List Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.	
Create New	Creates a new notification list. When you select **Create New**, you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.
Edit	Modifies settings within the notification list. When you select **Edit**, you are automatically redirected to the Notification List Settings page.
Delete	Removes a notification list from the list on the Notification List page. To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select **Delete**. To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select **Delete**.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in that content checksum list.
MMS Profiles	The MMS profile or profiles that are associated with
Comments	A description given to the MMS notification list.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List Settings

Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.

Name	If editing the name of a notification list, enter the new name in this field. You must select **OK** to save the change.
Comments	If you want to enter a comment, enter the comment in the field. You must select **OK** to save the change.
Create New	Creates a notification entry in the list. When you select **Create New**, you are automatically redirected to the New Entry page.
Edit	Modifies settings within a notification list. When you select **Edit**, you are automatically redirected to the Edit Entry page.

Delete	Removes a notification entry from the list on the page. To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select **Delete**. To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select **Delete**.
Enable	Enables a notification entry that is disabled.
Disable	Disables a notification entry so that it is not active and available for use, but it is not deleted.
Remove All Entries	Removes all notification entries that are listed on the Notification List Settings page.
Enable	Displays whether or not the checksum is enabled.
Virus Name/Profile	The name of the virus that was added to the list.
Entry Type	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
New Entry page	
Virus Name/Profile	Enter the virus name.
Entry Type	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
Enable	Select to enable the virus in the list.

Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action	Description
Log	Add a log entry indicating that a message flood has occurred. You must also enable logging for **MMS Scanning > Bulk Messages** in the **Logging** section of the MMS protection profile.
DLP Archive	Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.
All messages	All the messages that exceed the flood threshold will be saved in the DLP archive.
First message only	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.
Intercept	Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also quarantined for later examination. If the quarantine of intercepted messages is disabled, the **Intercept** action has no effect.
Block	Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will quarantined for later examination.
Alert Notification	If the flood threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS flood notification message. In the web-based manager when **Alert Notification** is selected it displays the fields to configure the notification.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Message flood configuration settings

The following are message flood configuration settings in **Security Profiles > Carrier > Message Flood**.

Message Flood	
Lists the large amount of messages that are being sent to you from outside sources.	
Delete	Removes messages from the list. To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select **Delete**. To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select **Delete**.
Remove All Entries	Removes all messages from the list.
Protocol	The protocol used.
MMS Profile	The MMS profile that is used.
Sender	The sender's email address.
Level	The level of severity of the message.
Count	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
Window Size (minutes)	The time in minutes.
Timer (minutes:seconds)	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
Page Controls	Use to navigate through the list.

Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

Duplicate message configuration settings

View duplicate messages in **Security Profiles > Carrier > Duplicate Message**.

Duplicate Message Lists duplicates of messages that were sent to you.	
Delete	Removes a message from the list. To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select **Delete**. To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select **Delete**.
Page Controls	Use to navigate through the list.
Remove All Entries	Removes all duplicate messages from the list.
Protocol	Either MM1 or MM4
Profile	The MMS profile that logs the detection.
Checksum	The checksum of the MMS message.
Status	Either flagged or blank. Flagged means that the actions defined in the MMS profile are taken. For more information, see "MMS bulk email filtering options".
Count	Displays the number of messages in the last window of time.
Window Size (minutes)	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
Timer (minutes:seconds)	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

Carrier Endpoint Filter Lists

A carrier endpoint filter list contains carrier endpoint patterns. A pattern can match one carrier endpoint or can use wildcards or regular expressions to match multiple carrier endpoints. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier endpoint in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in **Security Profiles > Carrier > Carrier Endpoint Filter Lists**.

Carrier Endpoint Filter Lists Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.	
Create New	Creates a new endpoint filter list. When you select **Create New**, you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
Edit	Modifies settings within an endpoint filter list in the list.
Delete	Removes an endpoint filter in the list. To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select **Delete**. To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select **Delete**.
Name	The name of the endpoint filter.
# Entries	The number of carrier endpoint patterns in each carrier endpoint filter list.
MMS Profiles	The MMS profile that the carrier endpoint filter list is added to.
Comments	A description about the endpoint filter.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Carrier Endpoint Filter Lists Settings

Provides settings for configuring an endpoint filter.

Name	The name you entered on the New List page, after selecting **Create New** on the Carrier Endpoint Filter page.
Comments	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
Create New	Creates a new endpoint filter list. When you select **Create New**, you are automatically redirected to the New Entry page.
Edit	Select to modify the settings of a pattern in the list.
Delete	Select to remove a pattern in the list.
Enable	Enables a disabled pattern in the list.
Disable	Disables a pattern in the list.
Remove All Entries	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
Enable	Indicates whether or not the pattern is enabled.

Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set **Pattern Type** to correspond to the pattern that you want to use.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Pattern Type	The type of pattern chosen.
New Entry page	
Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set **Pattern Type** to correspond to the pattern that you want to use.
Action(s)	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Content Archive	MMS messages from the carrier endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the carrier endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	Select a pattern type as one of Single Carrier Endpoint, Wildcard or Regular Expression. Wildcard and Regular Expression will match multiple patterns where Signle Carrier Endpoint matches only one.
Enable	Select to enable this carrier endpoint filter pattern.

GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

GTP profile configuration settings

The following are GTP profile configuration settings in **Security Profiles > Carrier > GTP Profile**.

GTP Profile	
Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.	
Create New	Creates a new GTP profile. When you select **Create New**, you are automatically redirected to the New page.
Edit	Modifies settings within a GTP profile in the list. When you select **Edit**, you are automatically redirected to Edit page.
Delete	Removes a GTP profile from the list. To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select **Delete**. To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select **Delete**.
Name	The name of the GTP profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New GTP Profile	
Provides settings for configuring a GTP profile.	

Name	Enter a name for the GTP profile.
General Settings	Configure general options for the GTP profile..
Message Type Filtering	Configure filtering for messages.
APN Filtering	Configure filtering options for APN.
IMSI Filtering	Configure filtering options for IMSI.
Advanced Filtering	Configure advanced filtering options.
IE removal policy	Configure IE removal policy options.
Encapsulated IP Traffic Filtering	Configure filtering options for encapsulated IP traffic.
Encapsulated Non-IP End User Address Filtering	Configure filtering options for encapsulated non-IP end user addresses.
Protocol Anomaly	Configure protocol anomaly options.
Anti-Overbilling	Configure anti-overbilling options.
Log	Configure log options.

General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

General Settings section of the New GTP Profile	
Sequence Number Validation	Enable to check that packets are not duplicated or out of order. GTP packets contain a Sequence Number field. This number tells the receiving GGSN the order of the packets it is receiving. Normally the GGSN compares this sequence number in the packets with its own sequence counter — if the two do not match, the packet is dropped. This sequence number validation can be off-loaded to the FortiOS Carrier freeing up resources on the GGSN.
GTP-in-GTP	Select **Allow** to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel. To block all GTP-in-GTP packets, select **Deny**.
Minimum Message Length	Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk. The default minimum message length is 0 bytes.
Maximum Message Length	Enter the maximum allowed length of a GTP packet in bytes. A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications. By default the maximum message length is 1452 bytes.
Tunnel Limit	Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed. This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided. The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.
Tunnel Timeout	Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After this hard timeout, the unit deletes the GTP tunnel. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels. The default is 86400 seconds, or 24 hours.

General Settings section of the New GTP Profile	
Control plane message rate limit	Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of **0** does not limit the message rate. GTP DoS attacks can include: • **Border gateway bandwidth saturation**: A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth. • **GTP flood**: A GSN can be flooded by illegitimate traffic
Handover Group	Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations. Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service. When the handover group is defined it acts like a whitelist with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.
Authorized SGSNs	Use **Authorized SGSNs** to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set **Authorized SGSNs** to this firewall address or address group. You can use **Authorized SGSNs** to allow packets from SGSNs that have a roaming agreement with your organization.
Authorized GGSNs	Use **Authorized GGSNs** to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set **Authorized GGSNs** to this firewall address or address group. You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

Message type filtering options

On the **New GTP Profile** page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the

settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand **Message Type Filtering** in the GTP profile.

APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- `<network_id>` is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- `[.mnc<mnc_int>.mcc<mcc_int>.gprs]` is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP **create pdp request** messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN.

You cannot add an APN when creating a new profile.

APN Filtering	
Enable APN Filter	Select to enable APN filtering.
Default APN Action	Select the default action for APN filtering. If you select **Allow**, all sessions are allowed except those blocked by individual APN filters. If you select **Deny**, all sessions are blocked except those allowed by individual APN filters.
Value	The APN to be filtered.
Mode	The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
Action	The type of action that will be taken.
Edit	Modifies the settings within the filter. When you select **Edit**, the Edit window appears, which allows you to modify the settings of the APN.
Delete	Removes the APN from the list within the table, in the APN Filtering section.
Add APN	Adds a new APN filter to the list. When you select **Add APN**, the New window appears, which allows you to configure the APN settings.
New APN page	
Value	Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value **internet*** would match all APNs that being with **internet**.
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action	Select **Allow** or **Deny**.

Basic filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP **Create pdp** request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

IMSI Filtering section of the New GTP Profile	
Enable IMSI Filter	Select to enable IMSI filtering.
Default IMSI Action	Select the default action for IMSI filtering. If you select **Allow**, all sessions are allowed except those blocked by individual IMSI filters. If you select **Deny**, all sessions are blocked except those allowed by individual IMSI filters.
APN	The APN that is part of the IMSI that will be filtered.
MCC-MNC	The MCC-MNC part of the IMSI that will be filtered.
Mode	The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Action	The type of action that will be taken.
Edit	Modifies settings to an IMSI filter. When you select **Edit**, the Edit window appears, which allows you to modify the IMSI filter's settings.
Delete	Removes an IMSI filter from within the table, in the IMSI Filtering section.
Add IMSI	Adds a new IMSI filter to the list. When you select **Add IMSI**, the New window appears, which allows you to configure IMSI filter settings.
New IMSI page	
APN	Enter the APN part of the IMSI to be filtered.
MCC-MNC	Enter the MCC-MCC part of the IMSI to be filtered.
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action	Select **Allow** or **Deny**.

Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
APN Restriction	yes	-	-	yes
IMEI-SV	yes	-	-	-
IMSI	yes	-	yes	-
RAI	yes	-	yes	-
RAT	yes	-	yes	-
ULI	yes	-	yes	-

When editing a GTP profile, select **Advanced Filtering > Add** to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering	
Enable	Select to enable advanced filtering.
Default Action	Select the default action for advanced filtering. If you select **Allow**, all sessions are allowed except those blocked by individual advanced filters. If you select **Deny**, all sessions are blocked except those allowed by individual advanced filters.
Messages	The messages, for example, Create PDP Context Request.
APN Restriction	The APN restriction.
RAT Type	The RAT types associated with that filter.
ULI	The ULI pattern.
RAI	The RAI pattern.
IMEI	The IMEI pattern.
Action	The action that will be taken.
Edit	Modifies the filter's settings. When you select **Edit**, the Edit window appears, which allows you to modify the filter's settings.
Delete	Removes a filter from the list.
Add	Adds a filter to the list. When you select **Add**, the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	
Messages	The PDP content messages this profile will match.
Create PDP Context Request	Select to allow create PDP context requests.
Create PDP Context Response	Select to allow create PDP context responses.
Update PDP Context Request	Select to allow update PDP context requests.
Update PDP Context Response	Select to allow update PDP context responses.

APN	Enter the APN.
APN Mode	Select an APN mode as one or more of • Mobile Station provied • Network provided • Subscription provied This field is only available when an APN has been entered.
Mobile Station provided	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did no verify the user's subscription to the network.
Subscription verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
APN Restriction	Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include: • all • Public-1 • Public-2 • Private-1 • Private-2
IMSI	Enter the IMSI.
MSISDN	Enter the MSISDN.
RAT Type	Optionally select the RAT type as any combination of the following: • Any • UTRAN • GERAN • Wifi • GAN • HSPA Some RAT types are GTPv1 specific.
ULI pattern	Enter the ULI pattern.
RAI pattern	Enter the RAI pattern.

IMEI pattern	Enter the IMEI pattern.
Action	Select either **Allow** or **Deny**.

Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).
- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

Information Element (IE) removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in "Advanced filtering options", prior to forwarding the messages to the HGGSN (proxy mode).

IE removal policy	
Enable	Select to enable this option.
SGSN address of message IE	The firewall address or address group that contains the SGSN addresses.
IEs to be removed	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
Add	Adds an IE removal policy. When you select **Add**, the New window appears, which allows you to configure the IE policy.
Edit	Modifies settings from within the IE removal policy. When you select **Edit**, the Edit window appears, which allows you to modify the settings within the policy.
Delete	Removes the IE removal policy from the list.
New IE policy page	
SGSN address	Select a firewall address or address group that contains SGSN addresses.
IEs to be removed	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see When to use encapsulated IP traffic filtering.

Expand **Encapsulated IP Traffic Filtering** in the GTP profile to reveal the options.

Encapsulated IP Traffic Filtering	
Enable IP Filter	Select to enable encapsulated IP traffic filtering options.
Default IP Action	Select the default action for encapsulated IP traffic filtering. If you select **Allow**, all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select **Deny**, all sessions are blocked except those allowed by individual encapsulated IP traffic filters.
Source	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.
Destination	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.
Action	The type of action that will be taken. Select to **Allow** or **Deny** encapsulated traffic between this source and Destination.
Edit	Modifies the source, destination or action settings.
Add IP Policy	Adds a new encapsulated IP traffic filter. When you select **Add IP Policy**, the New window appears which allows you to configure IP policy settings.
New (window)	
Source	Select the source firewall address or address group.
Destination	Select the destination firewall address or address group.
Action	Select **Allow** or **Deny**.

Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the “Assigned PPP DLL Protocol Numbers” sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering	
Enable Non-IP Filter	Select to enable encapsulated non-IP traffic filtering.
Default Non-IP Action	Select the default action for encapsulated non-IP traffic filtering. If you select **Allow**, all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select **Deny**, all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
Type	The type chosen, **AESTI** or **IETF.**
Start Protocol	The beginning protocol port number range.
End Protocol	The end of the protocol port number range.
Action	The type of action that will be taken.
Edit	Modify a non-IP filter's settings in the list. When you select **Edit**, the Edit window appears, which allows you to modify the Non-IP policy settings.
Delete	Remove a non-IP policy from the list.
Add Non-IP Policy	Add a new encapsulated non-IP traffic filter. When you select **Add Non-IP Policy**, you are automatically redirected to the New page.
New (window)	
Type	Select **AESTI** or **IETF**.
Start Protocol **End Protocol**	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: • 33 (0x0021) Internet Protocol • 35 (0x0023) OSI Network Layer • 63 (0x003f) NETBIOS Framing • 65 (0x0041) Cisco Systems • 79 (0x004f) IP6 Header Compression • 83 (0x0053) Encryption
Action	Select **Allow** or **Deny**.

Protocol Anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly	
Invalid Reserved Field	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as "Spare" and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
Reserved IE	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
Miss Mandatory IE	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.
Out of State Message	The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved. Best practices dictate that packets with reserved or undefined values will be filtered.
Out of State IE	GTP Packets with out of order Information Elements are discarded.
Spoofed Source Address	The End User Address Information Element in the PDP Context Create & Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.

Anti-Overbilling options

You can configure the FortiOS Carrier firewall to prevent overbilling subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand **Anti-Overbilling** in the GTP profile to reveal these settings.

Anti-Overbilling	
Gi Firewall IP Address	The IP address of the unit's interface configured as a Gi gateway.
Port	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
Interface	Select the unit interface configured as a Gi gateway.
Security Context ID	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile
- enable GTP logging when you configure log and report settings.

To enable GTP logging after a GTP profile has been configured

1. Go to **Log & Report > Log Config > Log Settings**.
2. Select **Event Logging**, and select **GTP service event**.
3. Select **Apply**.

Log	
Log Frequency	Enter the number of messages to drop between logged messages. An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the Carrier-enabled FortiGate unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged. Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.
Forwarded Log	Select to log forwarded GTP packets.
Denied Log	Select to log GTP packets denied or blocked by this GTP profile.
Rate Limited Log	Select to log rate-limited GTP packets.
State Invalid Log	Select to log GTP packets that have failed stateful inspection.
Tunnel Limit Log	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.

Extension Log	Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries: • IMSI • MSISDN • APN • Selection Mode • SGSN address for signaling • SGSN address for user data • GGSN address for signaling • GGSN address for user data
Traffic count Log	Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects. The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages. The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted. When a tunnel is deleted, the log entry contains: • Timestamp • Interface name (if applicable) • SGSN IP address • GGSN IP address • TID • Tunnel duration time in seconds • Number of messages sent to the SGSN • Number of messages sent to the GGSN

Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address

- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

MMS Security features

FortiOS Carrier includes all the Security features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

Why scan MMS messages for viruses and malware?
MMS virus scanning
Sender notifications and logging
MMS content-based Antispam protection
MMS DLP archiving

Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices.

Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install “Caribe”. Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**
- Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B, SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [spanish version]
- First Discovered In The Wild: July 04, 2007
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 23,320
- **SymbOS/Commwar.A!worm**
- Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS_COMWAR.A [Trend]
- First Discovered In The Wild: May 16 2005
- Impact Level: 1

- Virus Class: Worm
- Virus Name Size: 27,936

- Aliases: None
- First Discovered In The Wild: Oct 17 2005
- Impact Level: 1
- Virus Class: File Virus
- Virus Name Size: None

For the latest list of threats Fortinet devices detect, visit the FortiGuard Center.

MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to **Security Profiles > Carrier > MMS Profile**, select an existing or create a new profile, and expand **MMS Scanning**. See MMS scanning options.

This section includes:

- MMS virus monitoring
- MMS virus scanning blocks messages (not just attachments)
- Scanning MM1 retrieval messages
- Configuring MMS virus scanning
- Removing or replacing blocked messages
- Carrier Endpoint Block
- MMS Content Checksum
- Passing or blocking fragmented messages
- Client comforting
- Server comforting
- Handling oversized MMS messages

MMS virus monitoring

To enable MMS virus monitoring, expand **MMS Scanning** and enable **Monitor only** for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan** for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scanunits which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the Carrier-enabled FortiGate unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand **MMS Scanning** and select **Scan MM1 message retrieval**.

Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Configuring MMS virus scanning

To configure MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan**.

Once applied to a security policy, the MMS protection profile will then perform virus scans on all traffic accepted by that policy.

Removing or replacing blocked messages

To remove blocked messages, expand **MMS Scanning** and select **Remove Blocked** for the selected MMS types.

Select **Remove Blocked** remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message, select **Constant**.

If you only want to monitor blocked content, select **Monitor Only**.

Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSIDSN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

To enable carrier endpoint blocking - web-based manager

1. Create a carrier endpoint filter list.
2. Go to **Security Profiles > Carrier > MMS Profile**.
3. Select **Create New**, or select an existing profile to edit and select **Edit**.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable endpoint blocking on.
6. Select the carrier endpoint filter list to use in matching the endpoints to be blocked.

In MMS Profile, endpoints can only be blocked.

Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See Carrier endpoint filter lists configuration settings.

To create a carrier endpoint filter list - web-based manager

1. Go to **Security Profiles > Carrier > Carrier Endpoint Filter Lists**.
2. Select **Create New**.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select **OK**.
4. Select **Create New** to add one or more entries to the list.
5. Select **OK** to return to display the list of filter lists.

Configuring endpoint filter list entries

For each single endpoint or group of endpoints have part of their identifying information in common, you create an entry in the endpoint filter list.

For example a `blocked_clients` filter list may include entries for single endpoints added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

To configure an endpoint filter list entry - web-based manager

1. Select **Create New**.
2. Enter the following information and select **OK**.

Name	Name of endpoint filter list. Select this name in an MMS protection profile.
Comments	Optional description of the endpoint filter list.
Check/Uncheck All	Select the check box to enable all endpoint patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual endpoint patterns.
Pattern	The pattern that FortiOS Carrier uses to match with endpoints. The pattern can be a single endpoint or consist of wildcards or Perl regular expressions that will match more than one endpoint. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the endpoint pattern: **None** - No action is taken. **Block** - MMS messages from the endpoint are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS** - MMS messages from the endpoint are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown. **Exempt from all scanning** - MMS messages from the endpoint are delivered and are exempt from all MMS protection profile scanning.
Content Archive	MMS messages from the endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	The pattern type: **Wildcard**, **Regular Expression**, or **Single Endpoint**.
Enable	Select to enable this endpoint filter pattern.

Blocking network access based on endpoints

You can use endpoint IP filtering to block traffic from source IP addresses associated with endpoints. You can also configure FortiOS Carrier to record log messages whenever endpoint IP filtering blocks traffic. Endpoint IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure endpoint IP filtering, go to **Security Profiles > Carrier > IP Filter** and add endpoints to the IP filter list. For each endpoint you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add endpoint patterns to the endpoint IP filter list. You must enter complete and specific endpoints that are valid for your network.

The only action available is block. You cannot use endpoint IP filtering to exempt endpoints from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the endpoints in the IP filter list and extracts the source IP addresses for these endpoints. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by endpoint IP filtering.

For information about the carrier endpoints and the user context list, including how entries are added to and removed from this list.

MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see MMS Content Checksum.

To configure an MMS content checksum list

1. Go to **Security Profiles > Carrier > MMS Content Checksum**.
2. Select **Create New**.
3. Enter a name for the list of checksums, and select **OK**.
   You are taken to the edit screen for that new list.

4. Select ***Create New*** to add a checksum.
5. Enter the ***Name*** and ***Checksum***, and select **OK**.
   The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To to remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand **MMS Scanning** and select **MMS Content Checksum** for the selected MMS types. Select the checksum list to match.

Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.

The Interval is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Client comforting

In general, client comforting is available for for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the Carrier-enabled FortiGate unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the Carrier-enabled FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1. The client requests the file.
2. The Carrier-enabled FortiGate unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.
3. The Carrier-enabled FortiGate unit continues buffering the file from the server, and also sends 512 bytes to the client.
4. After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.
5. When the file has been completely buffered, the client has received the following amount of data:

   ```
   ca * (T/ci) bytes == 512 * (40/20) == 512 * 2 == 1024 bytes,
   ```

   where `ca` is the client comforting amount, `T` is the buffering time and `ci` is the client comforting interval.
6. If the file does not contain a virus, the Carrier-enabled FortiGate unit sends the rest of the file to the client. If the file is infected, the FortiGate closes the data connection but cannot send a message to the client.

Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The **Interval** is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Handling oversized MMS messages

Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

Sender notifications and logging

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is

unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- MMS notifications
- Replacement messages

And three details to consider for logging and notifying administrators:

- Logging and reporting
- MMS logging options
- SNMP

MMS notifications

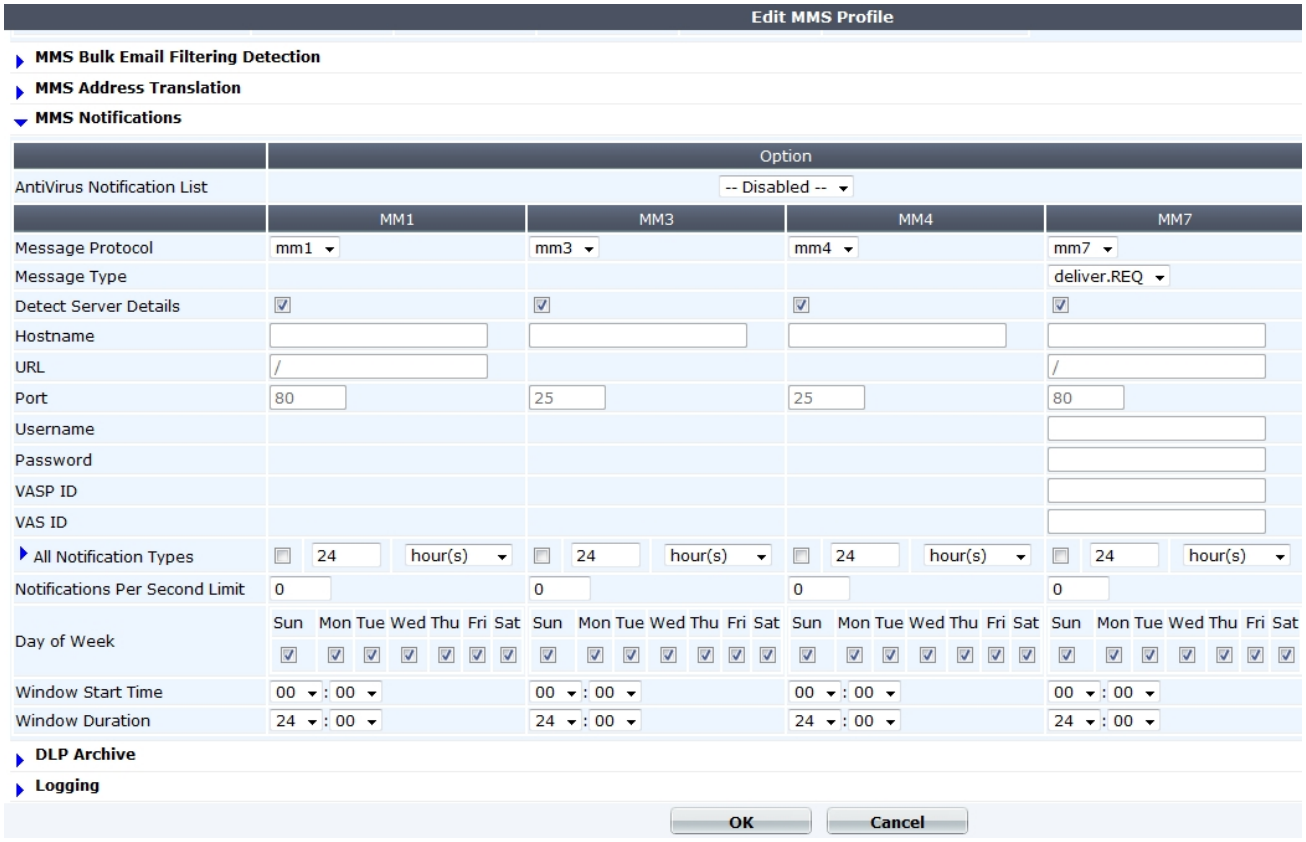
MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier Endpoint Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

Day of Week, **Window start time** and **Window Duration** define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

Notifications screen for FortiOS Carrier MMS Profile



For MMS Notification options, see MMS Notifications.

Replacement messages

FortiGate units send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In it's place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and reciever of the problem.

For example the replacement message **MM1 send-req file block message** is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours.` The two variables are replaced by the appropriate values.

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 deviceid=FGT5001ABCDEF1234 logid=0211060ABC type=virus
    subtype=infected level=warning src=10.1.2.3 dst=10.2.3.4 srcintf=port1 dstintf=port2
    service=mm1 status=blocked from="<sending MSISDN>" to="<receiving MSISDN>"
    file="eicar.com.txt" virus="EICAR_TEST_FILE" msg="The file eicar.com.txt is infected
    with EICAR_TEST_FILE. ref
    http://www.fortinet.com/VirusEncyclopedia/search/encyclopediaSearch.do?method=quickSea
    rchDirectly&virusName=EICAR_TEST_FILE"
```

Note that the **from** and **to** fields are samples and not real values.

MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to **Security Profiles > Carrier > MMS Profile**. Select **Create New** or select the **Edit** icon beside an existing profile. Expand **MMS Bulk AntiSpam Detection > Logging**. Complete the fields as described in the following table and select **OK**. For more a detailed list of options, see Logging.

SNMP

A simple SNMP trap will be generated to inform the operators' alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN, however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

MMS content-based Antispam protection

Expand **MMS Scanning** and select **Content Filter** in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

Configurable dictionary

You can create a dictionary of configurable terms and phrases using the CLI. The text of MMS messages will be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.

For each pattern you can select **Block** or **Exempt**.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.
- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed form the black list, users have to wait and they generally will be removed after a period without problem.

White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

Scores and thresholds

Each content pattern incudes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase “example” if it appears twice. To do this, add the “example” pattern, set action to block and score to 5. Keep the threshold at 10. If “example” is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

Configuring content-based antispam protection

To apply content-based antispam protection - CLI

```
config webfilter content
   edit <filter_table_number>
      set name <filter_table_name>
      config entries
         edit <phrase or regexp you want to block>
            set action {block | exempt}
            set lang <phrase language>
            set pattern-type {wildcard | regexp}
```

```
        set score <phrase score>
        set status {enable | disable}
    end
end
```

Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required. There are two types of sender notifications available in FortiOS Carrier: MMS notifications, and Replacement Messages.

MMS notifications

MMS notifications to senders are configured in **Security Profiles > Carrier > MMS Profile**, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see Notifying message flood senders and receivers and MMS Notifications.

Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different rec placement messages, the one common to all MMS protocols is the **MMS blocked content replacement message**. This is the message that the receiver of the message sees when their content is blocked.

MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content.

Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (**Summary**), or metadata and a copy of the associated file or message (**Full**).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for Carrier-enabled FortiGate units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

To configure MMS DLP archiving - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Select **Create New** or select the **Edit** icon beside an existing profile.
3. Expand **MMS Bulk AntiSpam Detection > Content Archive**.
4. Complete the fields as described in DLP Archive options.
5. Select **OK**.

Viewing DLP archives

You can view DLP archives from the Carrier-enabled FortiGate unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either **Log & Report > DLP Archive** or if you subscribed to the FortiCloud service, you can view log archives from there.

The **DLP Archive** menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to FortiCloud.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- **E-mail** to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- **Web** to view HTTP and HTTPS archives.
- **FTP** to view FTP archives.
- **IM** to view AIM, ICQ, MSN, and Yahoo! archives.
- **MMS** to view MMS archives.
- **VoIP** to view session control (SIP, SIMPLE and SCCP) archives.

If you need to view log archives in Raw format, select **Raw** beside the **Column Settings** icon.

Message flood protection

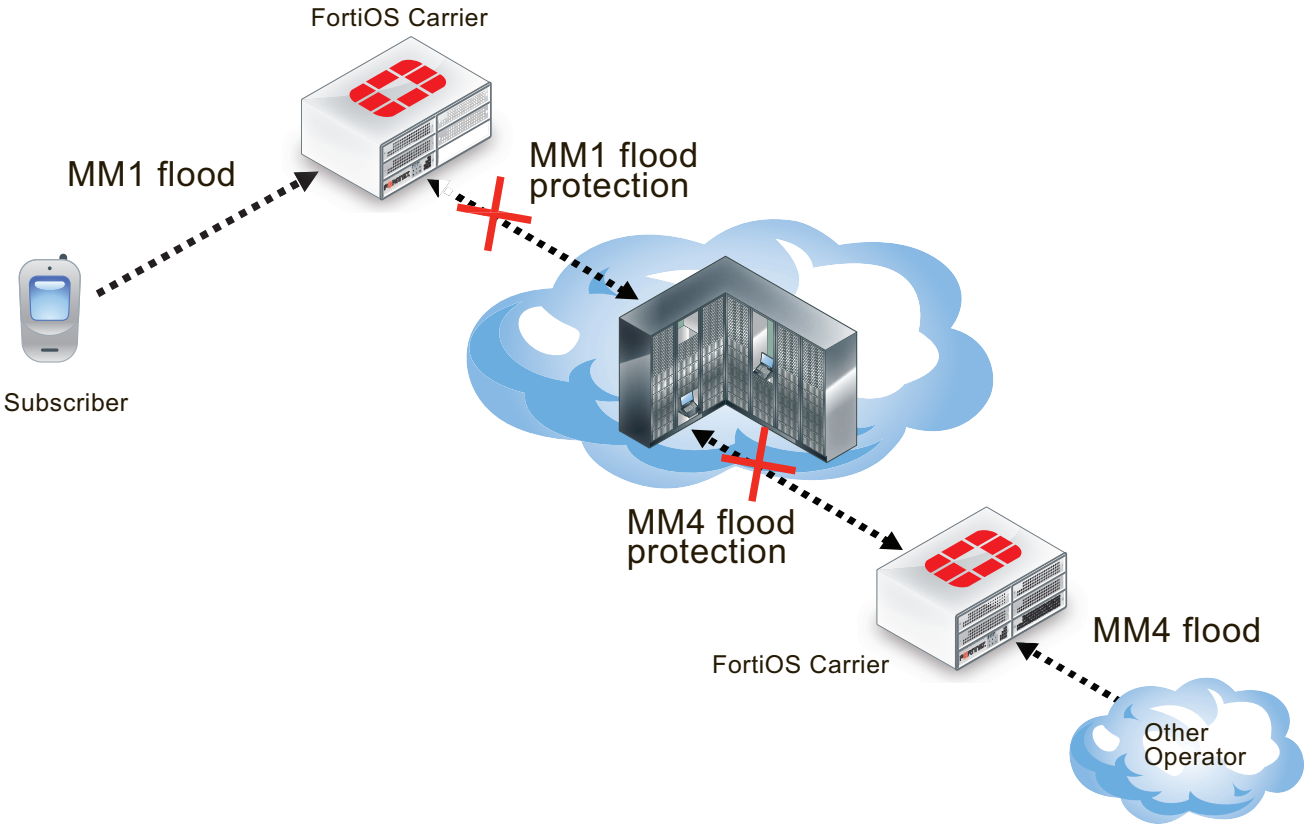
The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

Overview
Setting message flood thresholds
Notifying administrators of floods
Example — three flood threshold levels with different actions for each threshold
Notifying message flood senders and receivers
Viewing DLP archived messages
Order of operations: flood checking before duplicate checking
Bypassing message flood protection based on user's carrier endpoints
Configuring message flood detection
Sending administrator alert notifications

Overview

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

MM1 and MM4 flood protection



The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken. Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also enable logging for **MMS Scanning > Bulk Messages** in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

To configure MM1 message flood threshold - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Select **Create New**.
3. Enter `MM1 flood` for **Profile Name**.
4. Expand **MMS Bulk Email Filtering Detection**.
5. Enter the following information, and select **OK**.

MM1 (first column)	
Enable	Enable
Message Flood Window	60 minutes
Message Flood Limit	100
Message Flood Block Time	30 minutes
Message Flood Action	Block

To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status1 enable
         set window1 60
         set limit1 100
         set action1 block
         set block-time1 30
      end
   end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

Flood actions

When the Carrier-enabled FortiGate unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see Message Flood.

Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message **Flood Threshold 1** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	45
Message Flood Action	Log

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status1 enable
         set window1 30
         set limit1 45
         set action1 log
      end
```

```
    end
```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message **Flood Threshold 2** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	100
Message Block Time	15 minutes
Message Flood Action	Log, DLP archive First message only, Block

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status2 enable
         set window2 30
         set limit2 100
         set action2 block log archive-first
         set block-time2 15
      end
   end
```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message **Flood Threshold 3** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	200
Message Block Time	240 minutes
Message Flood Action	Log, Block, Alert Notification

Because you have selected the **Alert Notification** action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSIDSN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

Source MSISDN	5551234
Message Protocol	MM1
Hostname	mmscexample
URL	/
Port	80
Notifications Per Second Limit	0
Window Start Time	8:00
Window Duration	8:00
Day of Week	Mon, Tue, Wed, Thu, Fri, Sat
Interval	2 hours

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config notification alert-flood-1
         set alert-src-msisdn 5551234
         set set msg-protocol mm1
         set mmsc-hostname mmscexample
         set mmsc-url /
         set mmsc-port 80
         set rate-limit 0
         set tod-window-start 8:00
         set tod-window-duration 8:00
         set days-allowed monday tuesday wednesday thursday friday
         set alert-int 2
         set alert-int-mode hours
   end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select **MMS Bulk Email Filtering Detection > Recipient MSISDN > Create New**.

MSISDN	5554321
Flood Level 3	Select

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config notif-msisdn
         edit 5554321
            set threshold flood-thresh-3
      end
end
```

Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender's handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the **MM1 send-conf flood message** MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-flood
   set rsp-status ok
   set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-retrieve.conf message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the **MM1 retrieve-conf flood message** MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
   set subject "Message blocked"
   set message "Message temporarily blocked by carrier"
end
```

Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 flood message** MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK" for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
   set rsp-status ok
   set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as requiring as much storage.

To select only the first message in a flood for DLP archiving - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Edit an existing MMS Profile.
3. Expand the **MMS Bulk Email Filtering Detection** section, the **Message Flood** subsection, and the desired **Flood Threshold** subsection.
4. Next to **DLP Archive**, select **First message only** from the dropdown menu.
5. Select **OK**.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

Bypassing message flood protection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from message flood protection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns.

If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass message flood protection. This allows legitimate bulk messages, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier endpoints, see the User Authentication chapter of the FortiOS Handbook.

Configuring message flood detection

To have the Carrier-enabled FortiGate unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

Configure the MMS profile - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. If you are editing an MMS profile, select the **Edit** icon of the MMS profile.
   If you are creating a new MMS profile, select **Create New** and enter a profile name.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Message Flood**.
5. Expand **Flood Threshold 1**.
6. Select the **Enable** check box for MM1 messages, MM4 messages, or both.
7. In the **Message Flood Window** field, enter the length of time the Carrier-enabled FortiGate unit will keep track of the number of messages each subscriber sends.
   If the Carrier-enabled FortiGate unit detects the quantity of messages specified in the **Message Flood Limit** sent during the number of minutes specified in the **Message Flood Window**, a message flood is in progress.
8. In the **Message Flood Limit** field, enter the number of messages required to trigger the flood.
9. In the **Message Flood Block Time** field, enter the length of time a user will be blocked from sending messages after causing the message flood.
10. Select the message flood actions the Carrier-enabled FortiGate unit will take when the message flood is detected.
11. Select **OK**.

Configure the security policy - web-based manager

1. Go to **Policy**.
2. Select the **Edit** icon of the security policy that controls the traffic in which you want to detect message floods.
3. Select the **MMS Profile** check box to enable the use of a protection profile.
4. Select the MMS protection profile from the list.
5. Select **OK**.

Sending administrator alert notifications

When message floods are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- ***submit.REQ*** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- ***deliver.REQ*** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see MMS notifications.

To configure administrator alert notifications - web-based manager

1. Go to **Firewall Objects > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
   There are three message flood thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Message Flood Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.
   By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

   For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

   You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.
    For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.
    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for flood threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

Overview

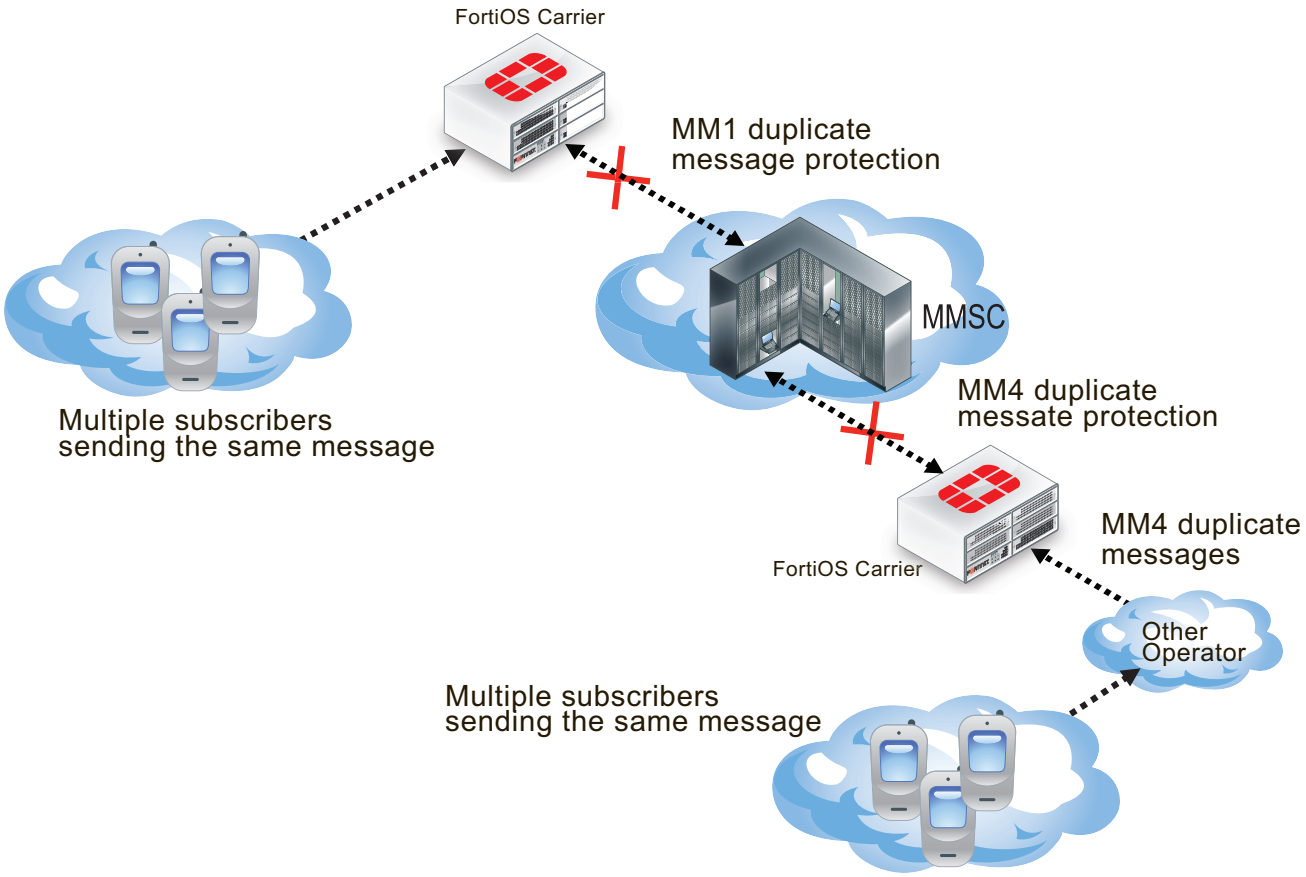
Messages from any sender to any recipient
Setting duplicate message thresholds
Duplicate message actions
Notifying duplicate message senders and receivers
Viewing DLP archived messages
Order of operations: flood checking before duplicate checking
Bypassing duplicate message detection based on user's carrier endpoints
Configuring duplicate message detection
Sending administrator alert notifications

Overview

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

MM1 and MM4 duplicate message protection



The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see Duplicate Message.

Using message fingerprints to identify duplicate messages

The Carrier-enabled FortiGate unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the Carrier-enabled FortiGate unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the Carrier-enabled FortiGate unit can save resources and time.

Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the Carrier-enabled FortiGate unit will recognize them as being the same.

Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

Duplicate message actions

When the Carrier-enabled FortiGate unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action		Description
Log		Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for **MMS Scanning > Bulk Messages** in the **Logging** section of the MMS protection profile.
DLP Archive		
	All messages	Save all the messages that exceed the duplicate threshold in the DLP archive.
	First message only	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
Intercept		Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the **Intercept** action has no effect.
Block		Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
Alert Notification		If the duplicate threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS duplicate message notification message.

Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the **MM1 send-conf duplicate message** MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize

the response status and message text for this message. The default response status is “Content not accepted”. To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm1 mm1-send-conf-dupe
   set rsp-status ok
   set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender’s handset would keep retrying). The m-retrieve.conf message is sent only when the `MM1duplicate` message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the **MM1 retrieve-conf duplicate message** MM1 replacement message (from the CLI the `mm1-retr-conf-dupe` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
   set subject "Message blocked"
   set message "Message temporarily blocked by carrier"
end
```

Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 duplicate message** MM4 replacement message (from the CLI the `mm4-dupe` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted” (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Forwarded OK”:

```
config system replacemsg mm4 mm4-dupe
   set rsp-status ok
   set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See Viewing DLP archived messages.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

Bypassing duplicate message detection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from duplicate message detection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass duplicate message detection. For more information about endpoints, see FortiOS Handbook User Authentication guide.

Configuring duplicate message detection

To have the Carrier-enabled FortiGate unit check for duplicate messages, configure the duplicate threshold in an MMS profile, and select the MMS profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of policies, with different GTP profiles.

In a complex configuration, there may be many security policies, each with a different MMS profile. For a simpler network, you may have many security policies all using the same MMS profile.

Sending administrator alert notifications

When duplicate messages are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

To configure administrator alert notifications - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
   There are three duplicate message thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Duplicate Message Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.

By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.

10. For **Day of Week**, select the days of the week to send notifications.
    For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.
    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for duplicate threshold alert notification.

Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features. Some features require longer explanations, and have their own chapters. The other features are addressed here.

GTP support on the Carrier-enabled FortiGate unit
Configuring General Settings on the Carrier-enabled FortiGate unit
Configuring Encapsulated Filtering in FortiOS Carrier
Configuring the Protocol Anomaly feature in FortiOS Carrier
Configuring Anti-overbilling in FortiOS Carrier
Logging events on the Carrier-enabled FortiGate unit

GTP support on the Carrier-enabled FortiGate unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the Carrier-enabled FortiGate unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as relayed network attacks.

A bookend configuration uses two Carrier-enabled FortiGate units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The Carrier-enabled FortiGate unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your Carrier-enabled FortiGate unit's GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

The Carrier-enabled FortiGate unit does more than just forward and route GTP packets over the network. It also performs:

- Packet sanity checking
- GTP stateful inspection
- Protocol anomaly detection and prevention
- HA
- Virtual domain support

Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attmpts to connect are detected, they are to be flagged immediately by the firewall .

Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See Configuring the Protocol Anomaly feature in FortiOS Carrier.

HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

GTP traffic will only flow without interruption on a HA switch if bidirectional GTP policies have been configured: an internal (GTP server) to external (all) UDP port GTP policy, and an external (all) to internal (GTP server) UDP port GTP policy. If either policy is missing then traffic may be interrupted until traffic flows in the opposite direction.

For more information on HA in FortiOS, see the High Availability (HA) Guide or the FortiOS Administration Guide.

Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single Carrier-enabled FortiGate unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, Carrier-enabled units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on HA in FortiOS, see the Virtual Domains (VDOMs) Guide.

Configuring General Settings on the Carrier-enabled FortiGate unit

To configure the GTP General Settings, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **General Settings** to configure settings. See General settings options.

Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is “wrapped up” in another protocol. This detail is important for firewalls because it requires “unwrapping” to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On Carrier-enabled FortiGate units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **Encapsulated IP Traffic Filtering** to configure settings. See Encapsulated IP traffic filtering options.

When to use encapsulated IP traffic filtering

The following are the typical cases that need encapsulated IP traffic filtering:

Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

Communication between mobile stations

Mobile stations on the same GPRS network are not able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or rewrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not used IP based addressing, so the Carrier-enabled FortiGate unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **Encapsulated Non-IP End User Address Filtering** to configure settings. See Encapsulated non-IP end user traffic filtering options.

Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions are not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand the **Protocol Anomaly** option. SeeProtocol Anomaly prevention options.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.
- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems, as well as other protocol anomalies, and drops the packets. All protocol anomaly options are set to **Deny** by default. However, you can change the policy to allow them.

Configuring Anti-overbilling in FortiOS Carrier

GPRS overbilling attacks can be prevented with a properly configured Carrier-enabled FortiGate unit.

Overbilling can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Overbilling can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

Anti-overbilling with FortiOS Carrier

The Carrier-enabled FortiGate unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the Carrier-enabled FortiGate unit involves:

- the administrator configuring the overbilling settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clearing the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents overbilling by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- **System > Network > Interface > Gi Gatekeeper** — edit an interface, and enable to monitor Gi anti-overbilling traffic on this interface
- **System > Admin > Settings > Gi Gatekeeper Settings** — set the context ID and port that anti-overbilling will take place on.
- **Security Profiles > Carrier > GTP Profile > Anti-Overbilling** — the IP address, port, interface and context ID to use for anti-overbilling measures.

For detailed options, see Anti-Overbilling options.

Logging events on the Carrier-enabled FortiGate unit

Logging on the Carrier-enabled FortiGate unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here.

To enable FortiOS Carrier logging, go to **Log&Report > Event Log**, and ensure **GTP service event** is enabled. Once this option is selected, the logging options under **Security Profiles > Carrier > GTP Profile** will be active.

To change FortiOS Carrier specific logging event settings, go to **Security Profiles > Carrier > GTP Profile** and edit a GTP profile. Expand the **Log** section to change the settings. For detailed options, see Log options.

The following information is contained in each log entry:

Timestamp	The time and date when the log entry was recorded
Source IP address	The sender's IP address.
Destination IP address	The reciever's IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.
Tunnel Identifier (TID) **Tunnel Endpoint Identifier (TEID)**	An identifier for the start and endpoints of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
Message type	For available message types, see Common message types on carrier networks.
Packet status	What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See Anti-overbilling with FortiOS Carrier on page 767. The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
Virtual domain ID or name	A Carrier-enabled FortiGate unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be `root`.
Reason to be denied if applicable	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

Common message types on carrier networks
Configuring message type filtering in FortiOS Carrier

Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-conversing GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol conversing between GTP and MAP.

Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP‘ (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

Unknown Action messages

If the system doesn’t know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set **Unknown Action messages** to deny for security reasons.

Configuring message type filtering in FortiOS Carrier

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

To configure GTP message type filtering - web-based manager

1. Go to **Security Profiles > Carrier > GTP Profile**.
2. Select **Create New**.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select **Message Type Filtering** to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to **Deny** for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select **OK** to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
   edit msg_type_filtering
      config message-filter
         set unknown-message-action deny
      next
   end
end
```

Message Type Fields

Each of the following message types can be allowed or denied by your Carrier-enabled FortiGate unit depending on your carrier network and GTP traffic.

Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.
Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements
Error Indication	GTP-U	Sent to the GGSN when a tunnel PDU is received for the following conditions: — No PDP context exists — PDP context is inactive — No MM context exists — GGSN deletes its PDP context when the message is received.
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN. **Reject Request -** Sent when the PDP context requested by the GGSN cannot be established.

Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	Sent by the GGSN to the HLR when a PDU reject message is received. The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected. The message contains the subscriber IMSI and Private Extension
Note MS GPRS Present Request/ Response	GTP-C	When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list. This message type contains subscriber IMSI, GSN Address and Private Extension

Mobility Management Messages

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state. SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	Forward the Routing Area Network (RAN) information. A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile

MBMS messages

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	Request to create an active MBMS context. The context will be pending until the response is received. Once active, the MBMS context allows the MS to receive data from a specific MBMS source
Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

IMSI on carrier networks
Other identity and location based information elements
Configuring APN filtering in FortiOS Carrier
Configuring IMSI filtering in FortiOS Carrier
Configuring advanced filtering in FortiOS Carrier

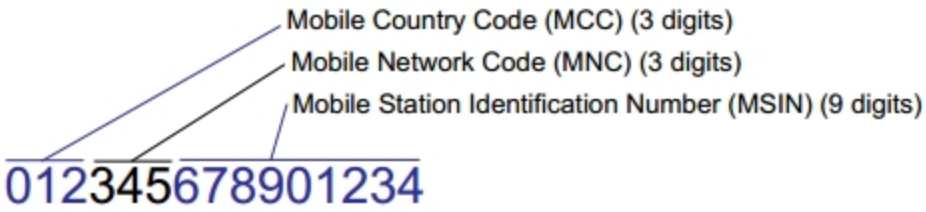
IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GMS or UTMS network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

IMSI codes



The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even through the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)
- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated.

Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.
- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user's location.

RAI is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone's IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: • user phone number (MSISDN) • what wireless technology the user employed • to get on the network (RAT type) • user location (ULI and RAI) • handset ID, such as for stolen phones (IMEI)

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering.

Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to **Security Profiles > Carrier > GTP Profile**. Select a profile or create a new one, and expand **APN filtering**.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

Enable APN Filter	Select to enable filtering based on APN value.
Default APN Action	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
Value	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example `*.mcc333.mcn111.gprs` would match all APNs from country `333` and carrier `111` on the gprs network.
Mode	Select one or more of the methods used to obtain APN values. Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection. Network provided - The APN comes from the carrier network. Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.
Action	One of allow or deny to allow or block traffic associated with this APN.
Delete icon	Select to remove this APN entry from the list.
Edit icon	Select to change the information for this APN entry.
Add APN	Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding APNs. A warning to this effect will be displayed when you select the **Add APN** button.

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to **Security Profiles > Carrier > GTP Profile** and expand **IMSI filtering**.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

Enable IMSI Filter	Select to turn on IMSI filtering.
Default IMSI Action	Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed. The default value is Allow.
APN	The Access Point Number (APN) to filter on. This field is optional.
MCC-MNC	The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used. This field is optional.
Mode	Select the source of the IMSI information as one or more of the following: **Mobile Station provided -** the IMSI number comes from the mobile station the mobile device is connecting to. **Network provided -** the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR. **Subscription Verified -** the IMSI number comes from the user's home network which has verified the information. While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.
Action	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
Delete Icon	Select the delete icon to remove this IMSI entry.
Edit Icon	Select the edit icon to change information for this IMSI entry.
Add IMSI	Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the **Add IMSI** button.

Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

Enable	Select to turn on advanced filtering.
Default Action	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .
Messages	Optionally select one or more types of messages this filter applies to: Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response. Selecting **Create PDP Context Response** or **Update PDP Context Response limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI,** and **IMEI fields.** To select **Update PDP Context Request**, **APN Restriction** must be set to **all**. Selecting **Update PDP Context Request disables the APN, MSISDN,** and **IMEI fields.** if all message types are selected, only the RAT Types of GAN and HSPA are available to select.
APN Restriction	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode.
RAT Type	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any.
ULI	The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network. The ULI is disabled when **Create PDP Context Response** or **Update PDP Context Response** messages are selected.
RAI	The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network. The RAI is disabled when **Create PDP Context Response** or **Update PDP Context Response** messages are selected.
IMEI	The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment. The IMEI is only available when **Create PDP Context Request** or no messages are selected.

Action	Select **Allow** or **Deny** as the action when this filter matches traffic. The default is Allow.
Delete Icon	Select to delete this entry from the list.
Edit Icon	Select to edit this entry.
Add	Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the **Add** button.

Troubleshooting

This section offers troubleshooting options for Carrier-related issues.

This section includes:

FortiOS Carrier diagnose commands
Applying IPS signatures to IP packets within GTP-U tunnels
GTP packets are not moving along your network

FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

```
diag firewall gtp <command>
```

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a whitelist of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.
noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.
path {list | flush}	Select list or flush. List the GTP related paths in FortiOS Carrier memory. Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexidecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles. You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.

stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list | flush}	Select one of list or flush. List lists all the GTP tunnels currently active. Flush clears the list of active GTP tunnels. This does not clear the clash counter displayed in the `stat` command.

Applying IPS signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signalling messages and error information. GTP-U uses UDP port 2152. Carrier-enabled FortiGate units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The Carrier-enabled FortiGate unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the Carrier-enabled FortiGate unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

To apply an IPS sensor to GTP-U tunnels

1. Go to **Security Profiles > Intrusion Protection > IPS Sensors** and select **Create New** to add an IPS Sensor.
2. Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.
   See the Intrusion Protection section of the FortiOS UTM Guide.
3. Go to **Policy & Objects > Policy > IPv4** and apply the IPS sensor to the security policy.
4. Go to **Policy & Objects > Policy > IPv4** and select Create New to add a security policy or select a security policy.
5. Configure the security policy to accept GTP traffic.
   In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.
6. Select the GTP profile within the security policy.
7. Configure any other required security policy settings.
8. Select **OK** to save the security policy.

GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- Attempt to identify the section of your network with the problem
- Ensure you have an APN configured
- Check the logs and adjust their settings if required
- Check the routing table
- Perform a sniffer trace
- Generate specific packets to test the network

Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a whitelist of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the Carrier-enabled FortiGate unit doesn't have the information it needs.

Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the Log Message Reference. For more information on logging in general, see the Logging and Reporting guide.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Ensure that all relevant event types are enabled under **Log & Report > Log Config > Log Settings.**

For more information on GTP related logging, see Logging events on the Carrier-enabled FortiGate unit.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the Carrier-enabled FortiGate unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your Carrier-enabled FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To check the routing table using the CLI

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

S* 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
S 2.0.0.0/8 [10/0] via 192.168.183.254, port2
C 10.142.0.0/23 is directly connected, port3
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your Carrier-enabled FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the Carrier-enabled FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Carrier-enabled FortiGate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the Carrier-enabled FortiGate unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your Carrier-enabled FortiGate unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as `port1` or `internal`. This can also be `any` to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. `none` indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever unit you stop it with `<CTRL C>`.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not be supported by Fortinet.

Chapter 7 - Compliance

Compliance

Introduction

Welcome and thank you for selecting Fortinet products for your network protection. This document discusses issues related to compliance, specifically Payment Card Industry Data Security Standard (PCI DSS).

This chapter contains the following topics:

- Before you begin
- How this guide is organized

Before you begin

Before you begin using this guide, please ensure that:

- You have administrative access to the web-based manager and/or CLI.
- The FortiGate unit is integrated into your network.
- The operation mode has been configured.
- The system time, DNS settings, administrator password, and network interfaces have been configured.
- Firmware, FortiGuard Antivirus and FortiGuard Antispam updates are completed.
- FortiGuard Analysis & Management Service is properly configured.

While using the instructions in this guide, note that administrators are assumed to be super_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

How this guide is organized

This FortiOS Handbook chapter contains the following sections:

Configuring FortiGate units for PCI DSS compliance on page 793 explains the Payment Card Industry Data Security Standard (PCI DSS). It provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements.

Configuring FortiGate units for PCI DSS compliance

This chapter provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements. There is also some description of other Fortinet products that can help you with PCI DSS compliance.The following topics are included in this section:

- Introduction to PCI DSS
- Network topology
- Security policies for the CDE network
- Wireless network security
- Protecting stored cardholder data
- Protecting communicated cardholder data
- Protecting the CDE network from viruses
- Monitoring the network for vulnerabilities
- Restricting access to cardholder data
- Controlling access to the CDE network

Introduction to PCI DSS

The primary source of information for your PCI DSS compliance program is the Payment Card Industry (PCI) Data Security Standard itself. Version 3.0 of the standard was published in November 2013. The following is only a brief summary of PCI DSS.

What is PCI DSS?

The Payment Card Industry Data Security Standard (PCI DSS) sets data handling requirements for organizations that hold, process, or exchange cardholder information.

What is the Cardholder Data Environment

Throughout the PCI DSS requirements, there are references to the Cardholder Data Environment (CDE). The CDE is the computer environment wherein cardholder data is transferred, processed, or stored, and any networks or devices directly connected to that environment.

PCI DSS objectives and requirements

PCI DSS consists of 7 control objectives and 12 requirements.

PCI DSS Control Objectives and Requirements

Control Objective	Requirement	Fortinet Solution
Build and Maintain a Secure Network and Systems	**1.** Install and maintain a firewall configuration to protect cardholder data	FortiGate firewall functionality. See Security policies for the CDE network.
	2. Do not use vendor - supplied defaults for system passwords and other security parameters	FortiDB vulnerability assessment and auditing FortiWeb web application password checking See Password complexity and change requirements.
Protect Cardholder Data	**3.** Protect stored cardholder data	FortiDB vulnerability assessment and monitoring FortiWeb web application firewall See Protecting stored cardholder data.
	4. Encrypt transmission of cardholder data across open, public networks	FortiGate IPsec VPN. See Protecting communicated cardholder data.
Maintain a Vulnerability Management Program	**5.** Protect all systems against malware and regularly update antivirus software or programs	FortiGate integrated AV FortiClient integrated AV FortiMobile integrated AV FortiMail integrated AV FortiGuard automated AV updates See Protecting the CDE network from viruses.
	6. Develop and maintain secure systems and applications	FortiDB vulnerability assessment, auditing and monitoring FortiWeb web application security See Monitoring the network for vulnerabilities.

Control Objective	Requirement	Fortinet Solution
Implement Strong Access Control Measures	**7.** Restrict access to cardholder data by business need-to-know	FortiDB vulnerability assessment, auditing and monitoring. See Restricting access to cardholder data.
	8. Identify and authenticate access to system components	FortiGate integrated database or hooks to Active Directory. See Controlling access to the CDE network.
	9. Restrict physical access to cardholder data	Fortinet professional services in partnership with partner solutions
Regularly Monitor and Test Networks	**10.** Track and monitor all access to network resources and cardholder data	FortiDB auditing and monitoring FortiAnalyzer event reporting See Monitoring the network for vulnerabilities.
	11. Regularly test security systems and processes	FortiDB vulnerability assessment See Monitoring the network for vulnerabilities.
Maintain an Information Security Policy	**12.** Maintain a policy that addresses information security for all personnel	FortiManager security policy management appliance

This chapter describes how the FortiGate unit's features can help your organization to be compliant with PCI DSS. Requirements that the FortiGate cannot enforce need to be met through organization policies with some means determined for auditing compliance.

Be sure to read the section, Wireless guidelines, below. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

Wireless guidelines

While wired networks usually connect fixed known workstations, wireless networks are more dynamic, introducing a different set of security concerns.

Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that unauthorized wireless networking has not been introduced into the CDE. Wireless networking could be introduced quite casually by adding a wireless device to a PC on the CDE network.

For all PCI DSS networks, whether they use wireless technology or not, the following requirement applies:

- Test for the presence of wireless access points by using a wireless analyzer at least quarterly or deploying a wireless IDS/IPS to identify all wireless devices in use. (11.1)

If your organization uses wireless networking outside the CDE network and the firewall prevents communication with the CDE network, the wireless network is outside the PCI DSS scope, but the firewall configuration must meet PCI DSS requirements.

If your organization uses wireless networking inside the CDE network, the wireless network is within the PCI DSS scope. For information about wireless network requirements, see Wireless network security.

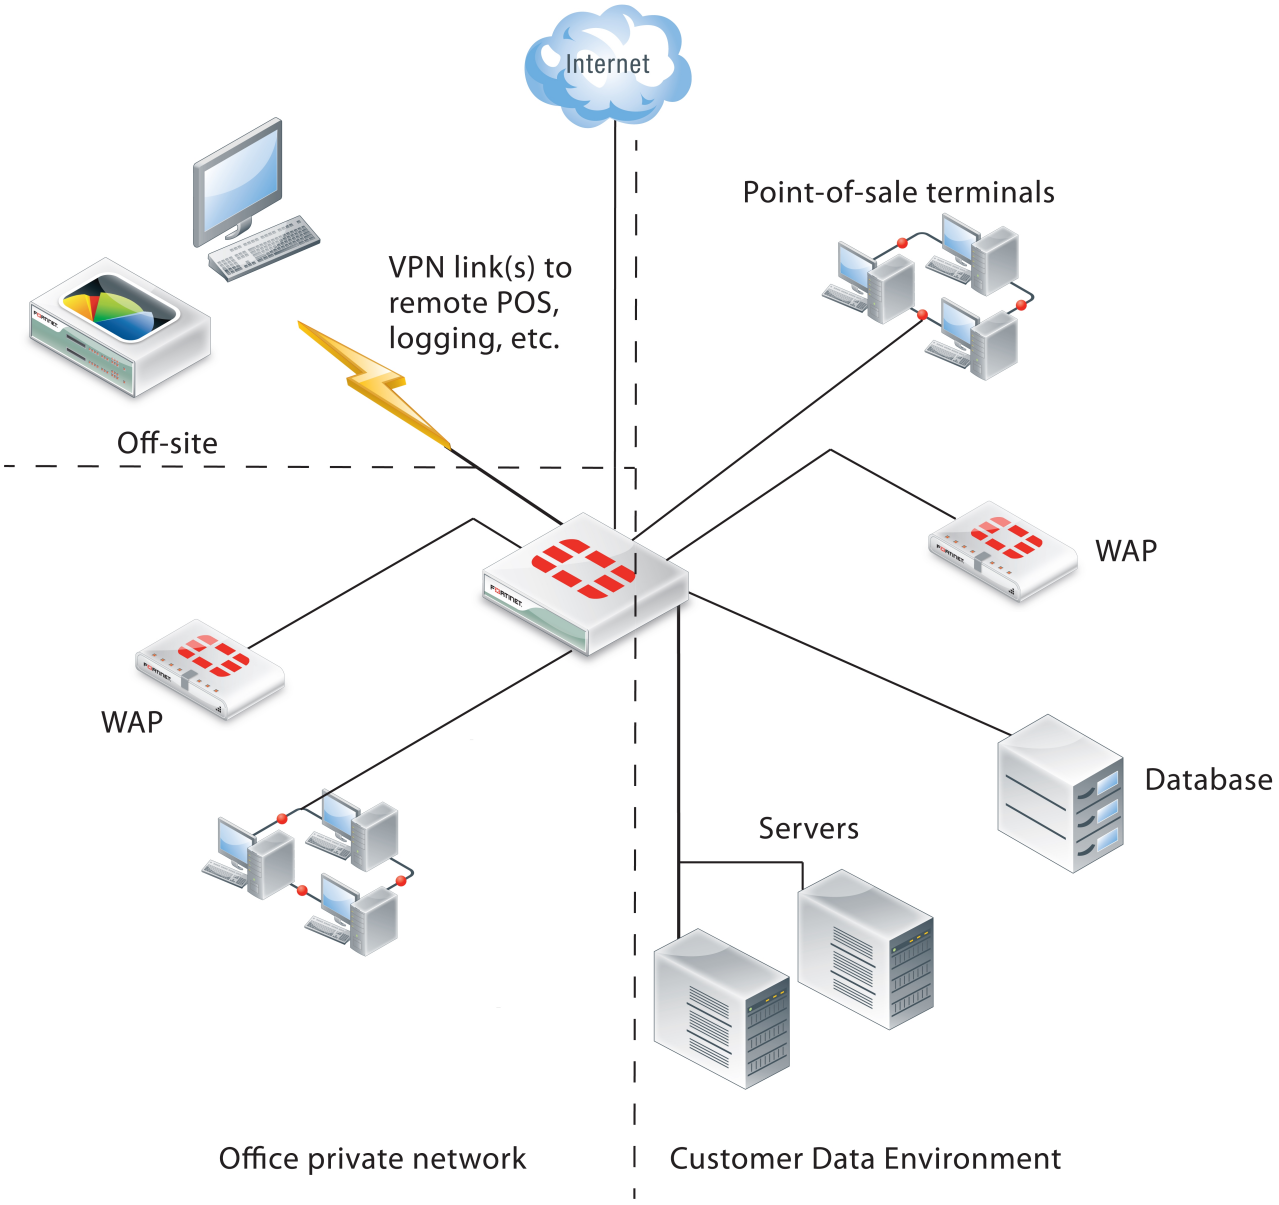
Network topology

The cardholder data environment must be protected against unauthorized access from the Internet and from other networks in your organization. FortiGate unit firewall functionality provides tight control over the traffic that can pass between the following network interfaces:

- Internet
- CDE wired LAN
- CDE wireless LAN
- Other internal networks

The figure below shows how the Cardholder Data Environment can be delineated in a typical network.

Enterprise network with a cardholder data environment



Internet

The FortiGate unit has at least one network interface connected to the Internet. If your organization uses more than one Internet service provider, there could be additional network interfaces that function as a route to the Internet.

The CDE wired LAN

The CDE network typically contains point-of-sale (POS) terminals, databases, and servers. The only security policies between the CDE network and the Internet should be for encrypted connections. For remote point-of-sale terminals or off-site databases, VPN connections are required and they should use strong encryption. For a web

server that handles online purchases, only HTTPS (SSL or TLS) connections can be permitted. The security policies that enable these connections should have the narrowest possible definitions for source address, destination address and service.

PCI DSS does not require the CDE network to be isolated from the rest of your corporate LAN. But isolating the CDE network reduces the scope of required data protection measures and may reduce the scope of PCI DSS assessments that are periodically required.

The CDE wireless LAN

Wireless networking is a special issue. Even if you do not use wireless technology you must monitor to ensure that unauthorized wireless access has not been added to the CDE network. For this purpose, the figure above shows a FortiAP device in the CDE. The FortiAP device can provide dedicated wireless monitoring, an access point, or both.

A small retail outlet could reduce costs by using a FortiWiFi unit, a FortiGate unit with integrated wireless networking. The FortiWiFi unit would have to be located where it could provide sufficient wireless monitoring (or access point) coverage for the entire premises.

Other internal networks

Other internal networks such as your office LAN, unless they provide connection to the CDE, are not subject to PCI DSS requirements.

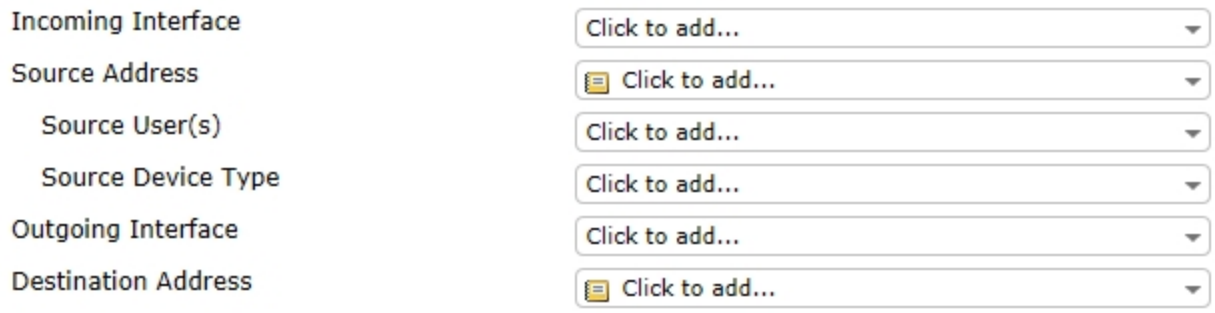
Security policies for the CDE network

The FortiGate unit's firewall functionality is ideally suited to PCI DSS requirement 1.2.1, "Restrict inbound and outbound traffic to that which is necessary for the cardholder data environment, and specifically deny all other traffic." Security policies control the source, destination, and type of traffic passing between networks.

The PCI DSS standard includes requirements to document your network topology and configuration. As part of that requirement, and to assist the auditing of your network, make use of the **Comment** field available in FortiGate security policies. Describe the purpose of each policy.

Controlling the source and destination of traffic

The source and destination are the first parameters you specify in a security policy. (Go to **Policy & Objects > Policy > IPv4** and select **Create New**.)



The **Interface** settings depend on network topology. The **Address** settings define the IP addresses to which the policy applies. These should be as narrow as possible, so that only the appropriate hosts are included. For

example, if the destination is a server with a single IP address, the named Destination Address should be defined as that single address, not the entire subnet on which the server resides.

Addresses are defined in **Policy & Objects > Objects > Addresses**. You can also define a new address by selecting **Create** from either the **Source Address** or **Destination Address** drop-down lists in a security policy. Some addresses will be used in several security policies, so it is best to plan ahead and define the addresses first.

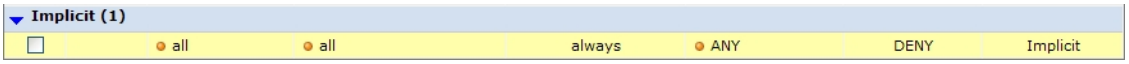
Controlling the types of traffic in the CDE

The **Service** setting in each security policy determines which types of traffic can pass based on protocol.

You can select a single protocol from the **Service** drop-down list. To add another protocol, select the green "+" button to access the **Service** drop-down list again. If several security policies will need the same list of services, consider creating a named service group. (Go to **Firewall Objects > Service > Groups**.) In the security policy, service groups are available at the bottom of the **Service** drop-down list.

The default deny policy

All traffic not specifically allowed by a security policy that you create is blocked by the Implicit policy listed at the bottom of the **Policy & Objects > Policy > IPv4** page.



You cannot delete this policy and you can edit the policy only to enable or disable logging of the traffic that it handles.

Wireless network security

Scanning for rogue access points is the minimum requirement for wireless security. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

If you use wireless networking, the wireless network is only within the PCI DSS scope if it can connect to the CDE.

On-wire detection of rogue APs

FortiGate units include an "on-wire" detection technique that correlates the SSID MAC addresses of the unknown access points with MAC addresses detected on your wired networks. This helps to differentiate unrelated neighboring APs from security-compromising unauthorized APs connected to your network.

Setting up rogue access point scanning

A FortiGate unit with a connected FortiAP unit can perform wireless scanning. Each of the FortiAP radios can act as a dedicated monitor or can perform scanning in the background while acting as a wireless access point.

Radio 1 operates in the 2.4GHz band and Radio 2 operates in the 5GHz band. Both bands should be monitored. The FortiAP unit(s) used for scanning must be located within the coverage area that would result if an access point were added to the CDE.

To configure rogue AP scanning in a FortiAP profile

1. Go to **WiFi Controller > WiFi Network > WIDS Profiles**.
   On some models, the menu is **WiFi & Switch Controller**.

2. Select an existing WIDS profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.
4. Select **Enable On-Wire Rogue AP Detection**.
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

Viewing the results of rogue AP scanning

Go to **WiFi Controller > Monitor > Rogue AP Monitor** to view information about detected wireless access points.

Logging the results of rogue AP scanning

To ensure that detection of rogue access points is logged, go to **Log & Report > Log Config > Log Settings** and enable logging for **WiFi activity event**.

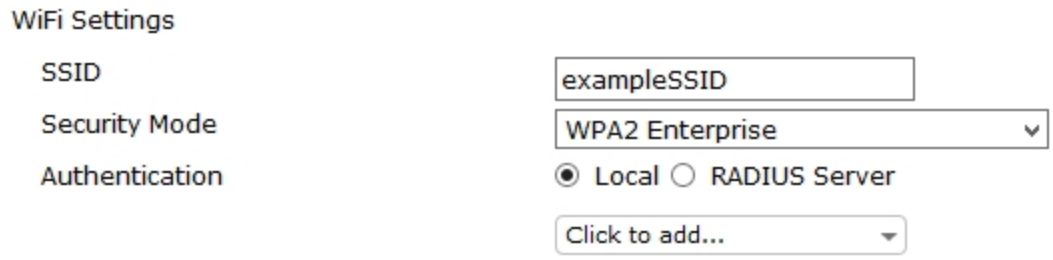
Securing a CDE network wireless access point

If your wireless network is within PCI DSS scope, it must meet the following requirements:

- Default settings such as SSID and passphrases must be changed.
- Use WPA/WPA2 security.
- Log wireless activity.

Setting wireless security

On FortiGate units, go to **WiFi Controller > WiFi Network > SSID** to configure wireless security settings for either a new or existing virtual access point.



The default SSID for the FortiAP is “fortinet”. You must change this.

The **Security Mode must** be set to one of the WPA/WPA2 modes. Both WPA or WPA2 clients can be served. In the CLI, you can optionally select exclusively WPA or WPA2 operation.

WPA/WPA2-Enterprise **Authentication** uses separate logon credentials for each user. Either FortiGate user group security or an external RADIUS server performs the authentication. Optionally, certificate-based security can also be applied. WPA/WPA2-Personal authentication requires a single pre-shared key that is used by all clients and is thus less secure.

For detailed information about wireless access points, see the Deploying Wireless Networks chapter of the FortiOS Handbook.

Logging wireless network activity

To ensure that wireless network activity is logged, go to **Log&Report > Log Config > Log Settings** and enable logging for **WiFi activity event**.

Protecting stored cardholder data

The Fortinet FortiDB and FortiWeb products can provide security for your sensitive cardholder data.

The Fortinet Database Security (FortiDB) device provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet website, www.fortinet.com.

The Fortinet FortiWeb Web Application Firewall deployed in front of public-facing web applications protects Web applications, databases, and the information exchanged between them. In particular, it addresses the PCI DSS requirements 6.5 and 6.6 regarding web application vulnerabilities such as cross-site scripting, SQL injection, and information leakage. For more information about this product, see the Fortinet website, www.fortinet.com.

Protecting communicated cardholder data

If cardholder data must be communicated over an untrusted network, such as the Internet, use the FortiGate unit's IPsec VPN capability to exchange the data securely. If you support customer online transactions, use HTTPS (SSL or TLS encryption) for security. The relevant PCI DSS requirement is:

- Use strong cryptography and security protocols (for example, SSL/TLS, IPSEC, SSH, etc.) to safeguard sensitive cardholder data during transmission over open, public networks. (4.1)

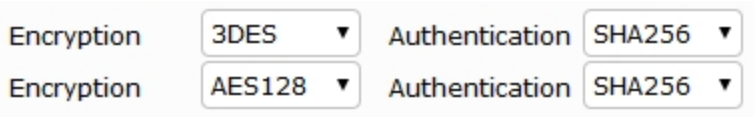
This does not prescribe particular cryptography, but it can be interpreted as a requirement to follow industry best practices.

Configuring IPsec VPN security

The security considerations for IPsec VPNs are encryption and authentication.

Encryption

Go to **VPN > IPsec > Tunnels** to configure an IPsec VPN. In both Phase 1 and Phase 2 parts of the configuration, you select the encryption to use.



These are advanced settings, overriding defaults that are not necessarily the strongest algorithms. VPNs negotiate over standards, so you can list multiple proposed algorithms. The VPN will use the strongest encryption that both ends support.

Choose strong encryption. The available encryption algorithms in descending order of strength are AES256, AES192, AES128, 3DES, DES. DES encryption is the weakest with only a 64-bit key and does not meet the 80-bit key length minimum that PCI DSS requires.

The message digest (authentication) algorithms in descending order of strength are SHA512, SHA384, SHA256, SHA1 and MD5. MD5 is particularly weak and should be avoided.

Authentication

VPN peers authenticate each other before establishing a tunnel. FortiGate units support two different authentication methods: pre-shared key and RSA signature (certificate). Certificates provide the best security. PCI DSS does not prohibit pre-shared keys, but you should limit access to the keys to the personnel who are responsible for the FortiGate units or other equipment at either end of the VPN.

Configuring SSL VPN security

The SSL VPN configuration includes a choice of encryption algorithm. You can only configure encryption key algorithms for SSL VPN in the CLI:

```
config vpn ssl settings
 set algorithm <low/medium/high>
end
```

The default option of **Medium** at **RC4 (128 bits)** is acceptable, but the **High** option, **AES (128/256 bits) and 3DES** is more secure. The **Low** option, **RC4 (64 bits), DES and higher** does not meet PCI DSS requirements.

Protecting the CDE network from viruses

PCI DSS requires the use of regularly updated antivirus protection. The antivirus functionality of the FortiGate unit protects both the FortiGate unit and the networks it manages. Workstations on these networks can be protected using FortiClient Endpoint Security. Both FortiGate and FortiClient antivirus protection can receive updates from Fortinet's FortiGuard service. Workstations can also use third-party antivirus applications with update services.

The FortiGate unit can enforce the use of antivirus software, denying unprotected workstations access to the network.

Enabling FortiGate antivirus protection

The antivirus profile must apply AV scanning to all protocols. You also need to enable SSL inspection to include secure protocols in antivirus scanning. The extended AV database contains the largest number of virus signatures.

To edit the antivirus profile

1. Go to **Security Profiles > AntiVirus**.
2. Edit the predefined profile or select **Create New**.
3. Set **Inspection Mode** to **Proxy**.
4. Ensure that all **Virus Scan and *Block*** check boxes are selected.
5. Select **Apply**.

To enable SSL inspection

1. Go to **Policy & Objects > Policy > SSL/SSH Inspection**.
   On some models, the option is **SSL Inspection**.
2. Set **Inspection Method** to **Full SSL Inspection**.
3. Set each listed protocol to **On** and then select **Apply**.

To select the extended antivirus database

The antivirus database is selectable using the CLI:

```
config antivirus settings
    set default-db extended
end
```

For detailed information about the Antivirus feature, see the Security Profiles chapter of the FortiOS Handbook.

Configuring antivirus updates

On the system dashboard, check the **License Information** widget. The **Support Contract** section should show Valid Contract and the contract expiry date. If your FortiGate unit is not registered, you need to visit the Fortinet Support web page (http://support.fortinet.com/) to register. Go to Product Registration and follow the instructions.

In the **FortiGuard Services** section, check the **Antivirus** field. If the service is unreachable, see the online Help for information about troubleshooting your connectivity to FortiGuard Services.

Enforcing firewall use on endpoint PCs

PCI DSS requires you to “install personal firewall software on any mobile and/or employee-owned devices that connect to the Internet when outside the network (for example, laptops used by employees), and which are also used to access the network. (1.4)” Consider using the Endpoint Control feature of the FortiGate unit to enforce use of this software.

Monitoring the network for vulnerabilities

There are several tools that can assist you in monitoring your network for vulnerabilities and provide evidence to the PCI DSS auditor of such monitoring.

FortiGate logs

FortiGate units can be configured to send logs to FortiAnalyzer unit. In a larger network, this enables you to collect log information in a central location from several FortiGate units.

Using the FortiOS Network Vulnerability Scan feature

As part of its security features, FortiGate units provide a Network Vulnerability Scan. You define assets to monitor, such as servers, workstations, or point-of-sale terminals. Then, the FortiGate unit scans those devices on a regular schedule. The scan checks TCP and UDP ports against a list of known vulnerabilities provided by FortiGuard Services. Scan settings determine how many of the ports are checked. Optionally, all ports are scanned.

Vulnerability scanning options in the web-based manager are now hidden by default. To enable vulnerability scanning, go to **System > Config > Features**, select **Show More**, turn on **Vulnerability Scan**, and select **Apply**.

To set up vulnerability scanning, go to **User & Device > Vulnerability Scan > Scan Definition**. To view scan logs, go to **User & Device > Vulnerability Scan > Vulnerability Result**. For more information, see Vulnerability Scan in the Managing Devices chapter of the FortiOS Handbook.

Monitoring with other Fortinet products

In addition to your FortiGate unit and its FortiOS firmware, there are several other Fortinet products that can assist your organization to comply with PCI DSS requirements.

Fortinet Database Security (FortiDB)

A FortiDB appliance or FortiDB software can provide vulnerability scanning and activity monitoring for your databases. For more information about this product, see the Fortinet website, www.fortinet.com.

FortiWeb Web Application Security

If your organization engages in e-Commerce, you can use FortiWeb Application Security to protect your web servers against attack. The FortiWeb application protects against HTTP and XML-based attacks, guards against attempts to deface your websites, and scans web servers for vulnerabilities. For more information about this product, see the Fortinet website, www.fortinet.com.

Restricting access to cardholder data

In addition to security policies and authentication governing access to the CDE, you can deploy the Fortinet Database Security (FortiDB) device, which provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet website, www.fortinet.com.

Controlling access to the CDE network

PCI DSS requires each user to be uniquely identified and authenticated. On the FortiGate unit, this applies to administrators and to users of SSL VPN and IPsec VPNs.

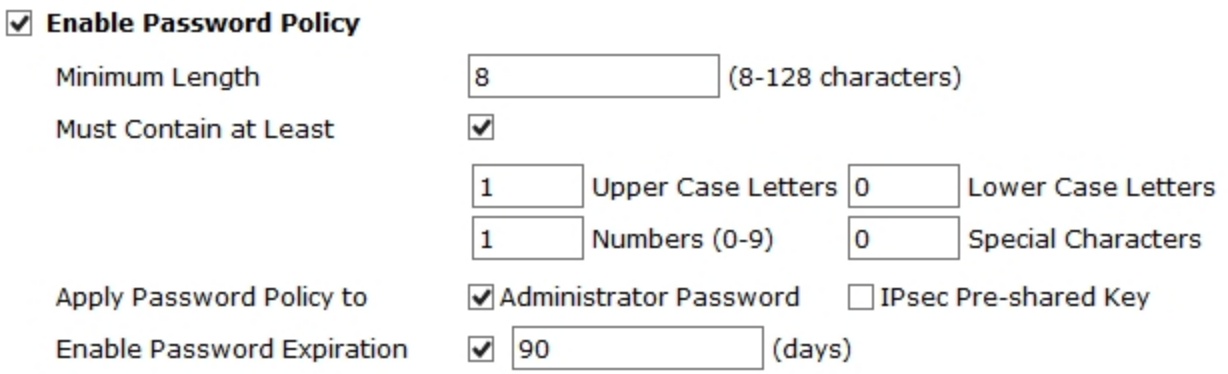
Password complexity and change requirements

By default, the FortiGate unit admin account has no password. Be sure to define a password.

PCI DSS password requirements are:

- Require a minimum length of at least seven characters. (8.2.3)
- Contain both numeric and alphabetic characters. (8.2.3)
- Change user passwords/passphrases at least every 90 days. (8.2.4)

To facilitate creation of compliant administrator passwords, you can set a password policy. Go to **System > Admin > Settings**. In the **Password Policy** section, enter the following and then select **Apply** at the bottom of the page.



Enable	Select the check box.
Minimum Length	8 or more. (Field does not accept a value less than 8.)
Must Contain	At minimum, set a required number of **Numerical Digits** and either **Upper Case Letters** or **Lower Case Letters**. Also setting a required number of **Non-alphabetic Letters** is acceptable.
Apply Password Policy to	Select **Administrator Password**.
Enable Password Expiration	Set to 90 days or less. The default is 90 days.

Note that the FortiGate password policy does not apply to user passwords. Both password complexity and password expiry for users would need to addressed by making them a policy in your organization.

Password non-reuse requirement

PCI DSS requires that passwords are not re-used to satisfy the change requirement:

- Do not allow an individual to submit a new password/phrase that is the same as any of the last four passwords/phrases he or she has used. (8.2.5)

FortiGate users don't set their own passwords. The super_admin administrators can and so can admins with appropriate access. There is, however, no FortiGate-based mechanism to enforce non re-use of passwords.

Administrator lockout requirement

PCI DSS requires a user account lockout for administrators to guard against unauthorized access attempts:

- Limit repeated access attempts by locking out the user ID after not more than six attempts. (8.1.6),
- Set the lockout duration to a minimum of 30 minutes or until an administrator enables the user ID. (8.1.7)

You can meet these requirements with the following CLI commands:

```
config system global
     set admin-lockout-threshold 6
     set admin-lockout-duration 1800
    end
```

The threshold can be less than 6 and the lockout duration can be more than 1800.

Administrator timeout requirement

PCI DSS requires:

- If a session has been idle for more than 15 minutes, require the user to re-authenticate to re-activate the terminal or session. (8.1.8)

By default, the idle timeout is five minutes. You can go to **System > Admin > Settings** and change the **Idle Timeout** timeout to any value up to the permitted value of 15 minutes.

Administrator access security

To accommodate the requirement for unique identification of each user, the generic admin account should either be assigned to only one administrator or not used at all. You can create an administrator account for each administrator in **System > Admin > Administrators**.

If an administrator always works from the same workstation, consider using the Trusted Host feature. The administrator will be able to log in only from a trusted IP address. You can define up to three trusted IP addresses per administrator.

Administrative access must also be enabled per network interface. Go to **System > Network > Interface** to edit the interface settings. Enable administrative access only on interfaces where you would expect the administrator to connect. Allow only secure connection protocols, HTTPS for web-based access, SSH for CLI access.

Remote access security

For remote access, PCI DSS requires two-factor authentication: a password and some other authentication, such as a smart token or certificate. This applies to employees, administrators, and third parties.

SSL VPN users

For SSL VPN users, implement two-factor authentication by requiring users to have a certificate in addition to the correct password. Go to **VPN > SSL > Settings**, enable **Require Client Certificate**, and then select **Apply**. For more information, see the SSL VPN chapter of the FortiOS Handbook.

IPsec VPN users

If users access your network using an IPsec VPN, you can implement two-factor authentication by enabling extended authentication (XAUTH). This requires the user to enter a password in addition to the VPN authentication provided by the certificate or pre-shared key. As PCI DSS requires each user to have a unique identifier, you should already have user accounts and user groups defined.

To configure XAUTH on your VPN

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the Convert to Custom Tunnel button).
3. Under **XAuth**, select the **Server Type** setting, which determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
   - **PAP Server** —Password Authentication Protocol.
   - **CHAP Server** — Challenge-Handshake Authentication Protocol.

- **Auto Server** —Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server. This option allows multiple source interfaces to be defined in an IPsec/IKE policy.

4. From the **User Group** list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here. For multiple source interfaces to be defined in the IPsec/IKE policy, select **Inherit Groups from Policy**.
5. Select **OK**.

Chapter 8 - Deploying Wireless Networks

This FortiOS Handbook chapter contains the following sections:

Introduction to wireless networking explains the basic concepts of wireless networking and how to plan your wireless network.

Configuring a WiFi LAN explains how to set up a basic wireless network, prior to deploying access point hardware.

Access point deployment explains how to deploy access point hardware and add it to your wireless network configuration.

Wireless Mesh explains how to configure a Wi-Fi network where access points are connected to the Wi-Fi controller wirelessly instead of by Ethernet.

Combining WiFi and wired networks with a software switch shows how to use the FortiAP Wi-Fi-Ethernet bridge feature.

Protecting the WiFi Network explains the Wireless Intrusion Detection System (WIDS).

Wireless network monitoring explains how to monitor your wireless clients and how to monitor other wireless access points, potentially rogues, in your coverage area.

Configuring wireless network clients explains how to configure typical wireless clients to work with a WPA-Enterprise protected network.

Wireless network examples provides two examples. The first is a simple Wi-Fi network using automatic configuration. The second is a more complex example of a business with two Wi-Fi networks, one for employees and another for guests or customers.

Using a FortiWiFi unit as a client explains how to use a FortiWiFi unit as a wireless client to connect to other Wi-Fi networks. This connection can take the place of an Ethernet connection where wired access to a network or to the Internet is not available.

Support for location-based services explains how Fortinet supports location-based services that collect information about devices near FortiGate-managed access points, even if the devices don't associate with the network.

Reference provides information about Wi-Fi radio channels.

Introduction to wireless networking

This chapter introduces some concepts you should understand before working with wireless networks, describes Fortinet's wireless equipment, and then describes the factors you need to consider in planning deployment of a wireless network.

Wireless concepts
Security
Authentication
Wireless networking equipment
Automatic Radio Resource Provisioning

Wireless concepts

Wireless networking is radio technology, subject to the same characteristics and limitations as the familiar audio and video radio communications. Various techniques are used to modulate the radio signal with a data stream.

Bands and channels

Depending on the wireless protocol selected, you have specific channels available to you, depending on what region of the world you are in.

- IEEE 802.11b and g protocols provide up to 14 channels in the 2.400-2.500 GHz Industrial, Scientific and Medical (ISM) band.
- IEEE 802.11a,n (5.150-5.250, 5.250-5.350, 5.725–5.875 GHz, up to 16 channels) in portions of Unlicensed National Information Infrastructure (U-NII) band

Note that the width of these channels exceeds the spacing between the channels. This means that there is some overlap, creating the possibility of interference from adjacent channels, although less severe than interference on the same channel. Truly non-overlapping operation requires the use of every fourth or fifth channel, for example ISM channels 1, 6 and 11.

The capabilities of your wireless clients is the deciding factor in your choice of wireless protocol. If your clients support it, 5GHz protocols have some advantages. The 5GHz band is less used than 2.4GHz and its shorter wavelengths have a shorter range and penetrate obstacles less. All of these factors mean less interference from other access points, including your own.

When configuring your WAP, be sure to correctly select the Geography setting to ensure that you have access only to the channels permitted for WiFi use in your part of the world.

For detailed information about the channel assignments for wireless networks for each supported wireless protocol, see Reference on page 913.

Power

Wireless LANs operate on frequencies that require no license but are limited by regulations to low power. As with other unlicensed radio operations, the regulations provide no protection against interference from other users who are in compliance with the regulations.

Power is often quoted in dBm. This is the power level in decibels compared to one milliwatt. 0dBm is one milliwatt, 10dBm is 10 milliwatts, 27dBm, the maximum power on Fortinet FortiAP equipment, is 500 milliwatts. The FortiGate unit limits the actual power available to the maximum permitted in your region as selected by the WiFi controller country setting.

Received signal strength is almost always quoted in dBm because the received power is very small. The numbers are negative because they are less than the one milliwatt reference. A received signal strength of -60dBm is one millionth of a milliwatt or one nanowatt.

Antennas

Transmitted signal strength is a function of transmitter power and antenna gain. Directional antennas concentrate the signal in one direction, providing a stronger signal in that direction than would an omnidirectional antenna.

FortiWiFi units have detachable antennas. However, these units receive regulatory approvals based on the supplied antenna. Changing the antenna might cause your unit to violate radio regulations.

Security

There are several security issues to consider when setting up a wireless network.

Whether to broadcast SSID

It is highly recommended to broadcast the SSID. This makes connection to a wireless network easier because most wireless client applications present the user with a list of network SSIDs currently being received. This is desirable for a public network.

Attempting to obscure the presence of a wireless network by not broadcasting the SSID does not improve network security. The network is still detectable with wireless network “sniffer” software. Clients search for SSIDs that they know, leaking the SSID. Refer to RFC 3370. Also, many of the latest Broadcom drivers do not support hidden SSID for WPA2.

Encryption

Wireless networking supports the following security modes for protecting wireless communication, listed in order of increasing security.

None — Open system. Any wireless user can connect to the wireless network.

WEP64 — 64-bit Web Equivalent Privacy (WEP). This encryption requires a key containing 10 hexadecimal digits.

WEP128 — 128-bit WEP. This encryption requires a key containing 26 hexadecimal digits.

WPA — 256-bit WiFi Protected Access (WPA) security. This encryption can use either the TKIP or AES encryption algorithm and requires a key of either 64 hexadecimal digits or a text phrase of 8 to 63 characters. It is also possible to use a RADIUS server to store a separate key for each user.

WPA2 — WPA with security improvements fully meeting the requirements of the IEEE 802.11i standard. Configuration requirements are the same as for WPA.

For best security use the WPA2 with AES encryption and a RADIUS server to verify individual credentials for each user. WEP, while better than no security at all, is an older algorithm that is easily compromised. With either WEP or WAP, changing encryption passphrases on a regular basis further enhances security.

Separate access for employees and guests

Wireless access for guests or customers should be separate from wireless access for your employees. This does not require additional hardware. Both FortiWiFi units and FortiAP units support multiple wireless LANs on the same access point. Each of the two networks can have its own SSID, security settings, firewall policies, and user authentication.

A good practice is to broadcast the SSID for the guest network to make it easily visible to users, but not to broadcast the SSID for the employee network.

Two separate wireless networks are possible because multiple virtual APs can be associated with an AP profile. The same physical APs can provide two or more virtual WLANs.

Captive portal

As part of authenticating your users, you might want them to view a web page containing your acceptable use policy or other information. This is called a captive portal. No matter what URL the user initially requested, the portal page is returned. Only after authenticating and agreeing to usage terms can the user access other web resources.

For more information about captive portals, see the Captive portals chapter of the FortiOS Authentication Guide.

Power

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. There are people who look for wireless networks and attempt to access them. If your office WLAN is receivable out on the public street, you have created an opportunity for this sort of activity.

Monitoring for rogue APs

It is likely that there are APs available in your location that are not part of your network. Most of these APs belong to neighboring businesses or homes. They may cause some interference, but they are not a security threat. There is a risk that people in your organization could connect unsecured WiFi-equipped devices to your wired network, inadvertently providing access to unauthorized parties. The optional On-Wire Rogue AP Detection Technique compares MAC addresses in the traffic of suspected rogues with the MAC addresses on your network. If wireless traffic to non-Fortinet APs is also seen on the wired network, the AP is a rogue, not an unrelated AP.

Decisions about which APs are rogues are made manually on the Rogue AP monitor page. For detailed information, see Wireless network monitoring on page 870.

Suppressing rogue APs

When you have declared an AP to be a rogue, you have the option of suppressing it. To suppress and AP, the FortiGate WiFi controller sends reset packets to the rogue AP. Also, the MAC address of the rogue AP is blocked in the firewall policy. You select the suppression action on the Rogue AP monitor page. For more information, see Wireless network monitoring on page 870.

Rogue suppression is available only when there is a radio dedicated to scanning. It will not function during background scanning for spectrum analysis.

Wireless Intrusion Detection (WIDS)

You can create a WIDS profile to enable several types of intrusion detection:

- Unauthorized Device Detection
- Rogue/Interfering AP Detection
- Ad-hoc Network Detection and Containment
- Wireless Bridge Detection
- Misconfigured AP Detection
- Weak WEP Detection
- Multi Tenancy Protection
- MAC OUI Checking

For more information, see Protecting the WiFi Network on page 867.

Authentication

Wireless networks usually require authenticated access. FortiOS authentication methods apply to wireless networks the same as they do to wired networks because authentication is applied in the firewall policy.

The types of authentication that you might consider include:

- user accounts stored on the FortiGate unit
- user accounts managed and verified on an external RADIUS, LDAP or TACACS+ server
- Windows Active Directory authentication, in which users logged on to a Windows network are transparently authenticated to use the wireless network.

This Wireless chapter of the FortiOS Handbook will provide some information about each type of authentication, but more detailed information is available in the Authentication chapter.

What all of these types of authentication have in common is the use of user groups to specify who is authorized. For each wireless LAN, you will create a user group and add to it the users who can use the WLAN. In the identity-based firewall policies that you create for your wireless LAN, you will specify this user group.

Some access points, including FortiWiFi units, support MAC address filtering. You should not rely on this alone for authentication. MAC addresses can be “sniffed” from wireless traffic and used to impersonate legitimate clients.

Wireless networking equipment

Fortinet produces two types of wireless networking equipment:

- FortiWiFi units, which are FortiGate units with a built-in wireless access point/client
- FortiAP units, which are wireless access points that you can control from any FortiGate unit that supports the WiFi Controller feature.

FortiWiFi units

A FortiWiFi unit can:

- Provide an access point for clients with wireless network cards. This is called Access Point mode, which is the default mode.

or

- Connect the FortiWiFi unit to another wireless network. This is called Client mode. A FortiWiFi unit operating in client mode can only have one wireless interface.

or

- Monitor access points within radio range. This is called Monitoring mode. You can designate the detected access points as Accepted or Rogue for tracking purposes. No access point or client operation is possible in this mode. But, you can enable monitoring as a background activity while the unit is in Access Point mode.

The Products section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiWiFi models that are currently available.

FortiAP units

FortiAP units are thin wireless access points are controlled by either a FortiGate unit or FortiCloud service.

FortiAP is a family of Indoor, Outdoor and Remote Access Point models supporting the latest single, dual, and triple stream MIMO 802.11ac and 802.11n technology, as well as 802.11g and 802.11a.

For large deployments, some FortiAP models support a mesh mode of operation in which control and data backhaul traffic between APs and the controller are carried on a dedicated WiFi network. Users can roam seamlessly from one AP to another.

In dual-radio models, each radio can function as an AP or as a dedicated monitor. The monitoring function is also available during AP operation, subject to traffic levels.

The Products section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiAP models that are currently available.

Automatic Radio Resource Provisioning

To prevent interference between APs, the FortiOS WiFi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature. When enabled in an access point profile, **Radio Resource Provision** measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.

Configuring a WiFi LAN

When working with a FortiGate WiFi controller, you can configure your wireless network before you install any access points. If you are working with a standalone FortiWiFi unit, the access point hardware is already present but the configuration is quite similar. Both are covered in this section.

Overview of WiFi controller configuration
Setting your geographic location
Creating a FortiAP Profile
Defining a wireless network interface (SSID)
Dynamic VLAN assignment
Configuring user authentication
Configuring firewall policies for the SSID
Configuring the built-in access point on a FortiWiFi unit

On FortiGate model 30D, web-based manager configuration of the WiFi controller is disabled by default. To enable it, enter the following CLI commands:

```
config system global
  set gui-wireless-controller enable
end
```

If you want to connect and authorize external APs, such as FortiAP units, see the next chapter, Access point deployment.

Overview of WiFi controller configuration

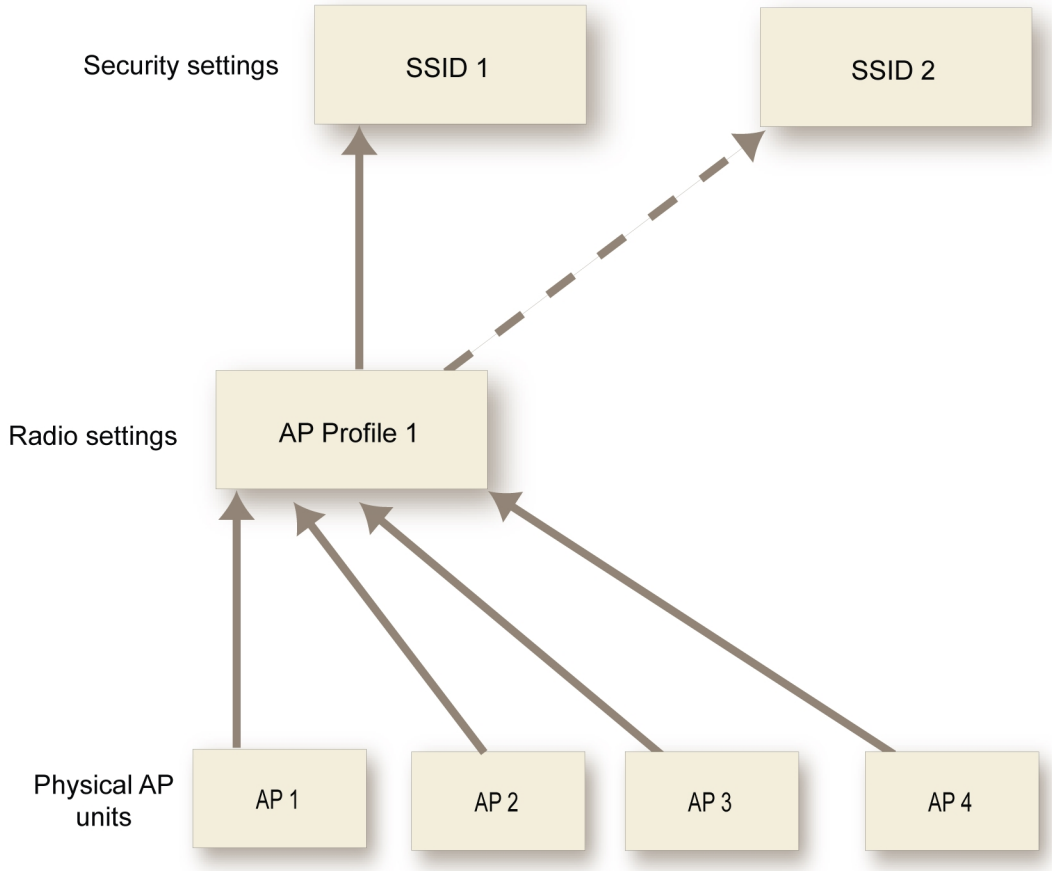
The FortiGate WiFi controller configuration is composed of three types of object, the SSID, the AP Profile and the physical Access Point.

- An **SSID** defines a virtual wireless network interface, including security settings. One SSID is sufficient for a wireless network, regardless how many physical access points are provided. You might, however, want to create multiple SSIDs to provide different services or privileges to different groups of users. Each SSID has separate firewall policies and authentication. Each radio in an access point can support up to 8 SSIDs.

A more common use of the term SSID is for the identifier that clients must use to connect to the wireless network. Each SSID (wireless interface) that you configure will have an SSID field for this identifier. In Managed Access Point configurations you choose wireless networks by SSID values. In firewall policies you choose wireless interfaces by their SSID name.

- An **AP Profile** defines the radio settings, such as band (802.11g for example) and channel selection. The AP Profile names the SSIDs to which it applies. Managed APs can use automatic profile settings or you can create AP profiles.
- **Managed Access Points** represent local wireless APs on FortiWiFi units and FortiAP units that the FortiGate unit has discovered. There is one managed access point definition for each AP device. An access point definition can use automatic AP profile settings or select a FortiAP Profile. When automatic profile settings are used, the managed AP definition also selects the SSIDs to be carried on the AP.

Conceptual view of FortiGate WiFi controller configuration



About SSIDs on FortiWiFi units

FortiWiFi units have a default SSID (wireless interface) named **wlan.** You can modify or delete this SSID as needed. As with external APs, the built-in wireless AP can be configured to carry any SSID.

The AP settings for the built-in wireless access point are located at **WiFi Controller > Managed Access Points > Local WiFi Radio**. The available operational settings are the same as those for external access points which are configured at **WiFi Controller > Managed Access Points > Managed FortiAPs**.

Process to create a wireless network

To set up your wireless network, you will need to perform the following steps:

- Make sure the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.
- Optionally, if you don't want to use automatic AP profile settings, configure a FortiAP profile, specifying the radio settings and the SSIDs to which they apply.
- Configure one or more SSIDs for your wireless network. The SSID configuration includes DHCP and DNS settings.
- Configure the user group and users for authentication on the WLAN.

- Configure the firewall policy for the WLAN.
- Optionally, customize the captive portal.
- Configure access points.
  Configuration of the built-in AP on FortiWiFi units is described in this chapter. Connection and configuration of FortiAP units is described in the next chapter, see Access point deployment on page 834.

Setting your geographic location

The maximum allowed transmitter power and permitted radio channels for WiFi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

To change the location setting - CLI

To change the country to France, for example, enter

```
config wireless-controller setting
   set country FR
end
```

To see the list of country codes, enter a question mark ('?') instead of a country code.

Before changing the country setting, you must remove all FortiAP Profiles. To do this, go to **WiFi Controller > WiFi Network > FortiAP Profiles**.

Creating a FortiAP Profile

A FortiAP Profile defines radio settings for a particular platform (FortiAP model). The profile also selects which SSIDs (virtual APs) the APs will carry. FortiAP units contain two radio transceivers, making it possible, for example, to provide both 2.4GHz 802.11b/g/n and 5GHz 802.11a/n service from the same access point. The radios can also be used for monitoring, used for the Rogue AP detection feature.

You can modify existing FortiAP profiles or create new ones of your own.

On FortiGate model 30D, web-based manager configuration of FortiAP Profiles is disabled by default. To enable AP profiles, enter the following CLI commands:

```
config system global
  set gui-ap-profile enable
end
```

To configure a FortiAP Profile - web-based manager

1. Go to **WiFi Controller > WiFi Network > FortiAP Profiles** and select **Create New**.
2. Enter a **Name** for the FortiAP Profile.
3. In **Platform**, select the FortiWiFi or FortiAP model to which this profile applies.
4. For each radio, enter:

Mode	Select the type of mode. **Disable** – radio disabled **Access Point** – the platform is an access point **Dedicated Monitor** – the platform is a dedicated monitor. See Wireless network monitoring on page 870.
Spectrum Analysis	Select to enable monitoring other APs in the background, even while operating as an AP. By default, spectrum analsis is disabled. See Wireless network monitoring on page 870.
WIDS Profile	Optionally, select a Wireless Intrusion Detection (WIDS) profile. See Protecting the WiFi Network on page 867.
Radio Resource Provision	Select to enable the radio resource provision feature. This feature measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.
Client Load Balancing	Select Frequency Handoff or AP Handoff as needed. See Access point deployment on page 834.
Band	Select the wireless protocols that you want to support. The available choices depend on the radio's capabilities. Where multiple protocols are supported, the letter suffixes are combined: "802.11bg" means 802.11b **and** 802.11g. For 802.11n, 802.11n_2.4G indicates 2.4GHz, 802.11n_5G indicates 5GHz. Note that on two-radio units such as the FortiAP-220B it is not possible to put both radios on the same band.
Select Channel Width	Select to enable 20MHz or 40MHz channel width for 802.11n-5G.
Short Guard Interval	Select to enable the short guard interval for 802.11n_5G with 40MHz channel width.
Channel	Select the channel or channels to include. The available channels depend on which IEEE wireless protocol you selected in **Band**. By default, all available channels are enabled.
Auto Tx Power Control	Optionally, enable automatic adjustment of transmit power, specifying minimum and maximum power levels.
TX Power	By default, the TX power is set to 100% of the maximum power permitted in your region. To change the level, drag the slider.
SSID	Choose the SSIDs (WiFi networks) that APs using this profile will carry.

Radio 1 settings are the same as Radio 2 settings except for the options for **Channel**.
Radio 2 settings are available only for FortiAP models with dual radios.

5. Select **OK**.

To configure a FortiAP Profile - CLI

This example configures a FortiAP-220B to use only Radio 2 for 802.11g operation applied to SSID example_wlan.

```
config wireless-controller wtp-profile
   edit guest_prof
      config platform
         set type 220B
      end
      config radio-2
         set mode ap
         set band 802.11g
         set vaps example_wlan
      end
   end
```

Defining a wireless network interface (SSID)

You begin configuring your wireless network by defining one or more SSIDs to which your users will connect. When you create an SSID, a virtual network interface is also created with the **Name** you specified in the SSID configuration. You can configure the settings of an existing SSID in either **WiFi Controller > WiFi Network > SSID** or **System > Network > Interface**.

To create a new SSID

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Fill in the SSID fields as described below.

To configure the settings of an existing SSID

1. Either
   - Go to **WiFi Controller > WiFi Network > SSID**.

   or

   - Go to **System > Network > Interfaces**.
     WiFi interfaces list the SSID beside the interface **Name**.
2. Edit a WiFi interface, modifying the SSID fields as needed.

SSID fields

Interface Name	Enter a name for the SSID interface.
Type	WiFi SSID.
Traffic Mode	**Tunnel to Wireless Controller** — Data for WLAN passes through WiFi Controller. This is the default. **Local bridge with FortiAP's Interface** — FortiAP unit Ethernet and WiFi interfaces are bridged. **Mesh Downlink** — Radio receives data for WLAN from mesh backhaul SSID.
IP/Network Mask	Enter the IP address and netmask for the SSID.
IPv6 Address	Enter the IPv6 address. This is available only when IPv6 has been enabled on the unit.
Administrative Access	Select which types of administrative access are permitted on this SSID.
IPv6 Administrative Access	If you have IPv6 addresses, select the permitted IPv6 administrative access types for this SSID.
DHCP Server	Select **Enable** to enable a DHCP server and define IP address ranges to assign to clients or to relay DHCP requests to another server. If the unit is in transparent mode, the DHCP server settings will be unavailable. For more information, see Configuring DHCP for WiFi clients on page 823.
WiFi Settings	
SSID	Enter the SSID. By default, this field contains `fortinet`.
Security Mode	Select the security mode for the wireless interface. Wireless users must use the same security mode to be able to connect to this wireless interface. Additional security mode options are available in the CLI. For more information, see Configuring security on page 824.
	Captive Portal – authenticates users through a customizable web page.
	WPA2-Personal – WPA2 is WiFi Protected Access version 2. There is one pre-shared key (password) that all users use.
	WPA2-Personal with Captive Portal – The user will need to know the pre-shared key and will also be authenticated through the custom portal.
	WPA2-Enterprise – similar to WPA2-Personal, but is best used for enterprise networks. Each user is separately authenticated by user name and password.

Pre-shared Key	Available only when **Security Mode** is **WPA2-Personal**. Enter the encryption key that the clients must use.
Authentication	Available only when **Security Mode** is **WPA2-Enterprise**. Select one of the following: **RADIUS Server** — Select the RADIUS server that will authenticate the clients. **Usergroup** – Select the user group(s) that can authenticate.
Portal Type	Available only when **Security Mode** is **Captive Portal**. Choose the captive portal type. Authentication is available with or without a usage policy disclaimer notice.
Authentication Portal	**Local** - portal hosted on the FortiGate unit **Remote** - enter FQDN or IP address of external portal
User Groups	Select permitted user groups.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the listed portal pages to edit them.
User Groups	Available only when **Security Mode** is **Captive Portal**. Select the user groups that can authenticate. To select a user group, select the group in **Available** and then use the -> arrow to move that group to **Selected**. To remove a user group from **Selected**, select the group and then use the <- arrow to move the group back to **Available**.
Redirect after Captive Portal	Optionally, select **Specific URL** and enter a URL for user redirection after captive portal authentication. By default, users are redirected to the URL that they originally requested.
Allow New WiFi Client Connections When Controller Is Down	This option is available for local bridge SSIDs with WPA-Personal security. See Combining WiFi and wired networks with a software switch on page 855.
Broadcast SSID	Optionally, disable broadcast of SSID. By default, the SSID is broadcast. For more information, see Introduction to wireless networking on page 810.
Block Intra-SSID Traffic	Select to enable the unit to block intra-SSID traffic.
Maximum Clients	Select to limit the number of clients permitted to connect simultaneously. Enter the limit value.

Split Tunneling	Select to enable some subnets to remain local to the remote FortiAP. Traffic for these networks is not routed through the WiFi Controller. Specify split-tunnel networks in the FortAP Profile. See Split tunneling on page 861.
Optional VLAN ID	Enter the ID of the VLAN this SSID belongs to. Enter 0 for non-VLAN operation.
Device Management	Select **Detect and Identify Devices** if you want to monitor the device types using this interface or create device identity policies involving this interface. Optionally, enable **Add New Devices to Vulnerability Scan List**.
Enable Explicit Web Proxy	Select to enable explicit web proxy for the SSID.
Listen for RADIUS Accounting Messages	Enable if you are using RADIUS-based Single Sign-On (SSO).
Secondary IP Address	Optioanally, enable and define secondary IP addresses. Administrative access can be enabled on secondary interfaces.
Comments	Enter a description or comment for the SSID.

To configure a virtual access point (SSID) - CLI

This example creates an access point with SSID “example” and WPA2-Personal security. The wireless interface is named example_wlan.

```
config wireless-controller vap
   edit example_wlan
      set ssid "example"
      set broadcast-ssid enable
      set security wpa2-only-personal
      set passphrase "hardtoguess”
      set vdom root
   end
config system interface
   edit example_wlan
      set ip 10.10.120.1 255.255.255.0
   end
```

Configuring DHCP for WiFi clients

Wireless clients need to have IP addresses. If you use RADIUS authentication, each user’s IP address can be stored in the Framed-IP-Address attribute. Otherwise, you need to configure a DHCP server on the WLAN interface to assign IP addresses to wireless clients.

To configure a DHCP server for WiFi clients - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and edit your SSID entry.
2. In **DHCP Server** select **Enable**.
3. In **Address Range**, select **Create New**.

4. In the **Starting IP** and **End IP** fields, enter the IP address range to assign.
   The address range needs to be in the same subnet as the wireless interface IP address, but not include that address.
5. Set the **Netmask** to an appropriate value, such as 255.255.255.0.
6. Set the **Default Gateway** to **Same as Interface IP**.
7. Set the **DNS Server** to **Same as System DNS**.
8. If you want to restrict access to the wireless network by MAC address, see "Defining a wireless network interface (SSID)" on page 826.
9. Select **OK**.

To configure a DHCP server for WiFi clients - CLI

In this example, WiFi clients on the example_wlan interface are assigned addresses in the 10.10.120.2-9 range to connect with the WiFi access point on 10.10.120.1.

```
config system dhcp server
   edit 0
      set default-gateway 10.10.120.1
      set dns-service default
      set interface example_wlan
      set netmask 255.255.255.0
      config ip-range
         edit 1
            set end-ip 10.10.120.9
            set start-ip 10.10.120.2
         end
      end
```

You cannot delete an SSID (wireless interface) that has DHCP enabled on it.

Configuring security

Using the web-based manager, you can configure Captive Portal security or WiFi Protected Access version 2 (WPA2) security modes WPA2-Personal and WPA2-Enterprise. Using the CLI, you can also choose WPA/WPA2 modes that support both WPA version 1 and WPA version 2.

WPA2 security with a pre-shared key for authentication is called WPA2-Personal. This can work well for one person or a small group of trusted people. But, as the number of users increases, it is difficult to distribute new keys securely and there is increased risk that the key could fall into the wrong hands.

A more secure form of WPA2 security is WPA2-Enterprise. Users each have their own authentication credentials, verified through an authentication server, usually RADIUS. FortiOS can also authenticate WPA2-Enterprise users through its built-in user group functionality. FortiGate user groups can include RADIUS servers and can select users by RADIUS user group. This makes possible Role-Based Access Control (RBAC).

By default, WPA2 security encrypts communication using Advanced Encryption Standard (AES). But some older wireless clients support only Temporal Key Integrity Protocol (TKIP) . You can change the encryption to TKIP or negotiable TKIP-AES in the CLI. For example, to accomodate clients with either TKIP or AES, enter:

```
config wireless-controller vap
   edit example_wlan
      set security wpa-personal
```

```
      set passphrase "hardtoguess"
      set encrypt TKIP-AES
   end
```

Captive Portal security connects users to an open web portal defined in replacement messages. To navigate to any location beyond the web portal, the user must pass FortiGate user authentication.

WPA-Personal security

WPA2-Personal security setup requires only the preshared key that you will provide to your clients.

To configure WPA2-Personal security - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Personal**.
3. In **Pre-shared Key**, enter a key between 8 and 63 characters long.
4. Select **OK**.

To configure WPA2-Personal security - CLI

```
config wireless-controller vap
   edit example_wlan
      set security wpa2-personal
      set passphrase "hardtoguess"
   end
```

WPA-Enterprise security

If you will use FortiOS user groups for authentication, go to **User & Device > User > User Groups** and create those groups first. The groups should be Firewall groups.

If you will use a RADIUS server to authenticate wireless clients, you must first configure the FortiGate unit to access the RADIUS server.

To configure FortiGate unit access to the RADIUS server - web-based manager

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
   edit exampleRADIUS
      set auth-type auto
      set server 10.11.102.100
      set secret aoewmntiasf
   end
```

To configure WPA-Enterprise security - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Enterprise**.
3. In **Authentication**, do one of the following:
   - If you will use a RADIUS server for authentication, select **RADIUS** Server and then select the RADIUS server.
   - If you will use a local user group for authentication, select **Local** and then select the user group(s) permitted to use the wireless network.
4. Select **OK**.

To configure WPA-Enterprise security - CLI

```
config wireless-controller vap
   edit example_wlan
      set security wpa2-enterprise
      set auth radius
      set radius-server exampleRADIUS
   end
```

Captive Portal security

Captive Portal security provides an access point that initially appears open. The wireless client can connect to the AP with no security credentials. The AP responds to the client's first HTTP request with a web page requesting user name and password. Until the user enters valid credentials, no communication beyond the AP is permitted.

For more information about captive portals, see the Captive Portal chapter of the Authentication Guide.

Adding a MAC filter

On each SSID, you can create a MAC address filter list to either permit or exclude a list of clients identified by their MAC addresses.

This is actually not as secure as it appears. Someone seeking unauthorized access to your network can obtain MAC addresses from wireless traffic and use them to impersonate legitimate users. A MAC filter list should only be used in conjunction with other security measures such as encryption.

To configure a MAC filter - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and edit your SSID entry.
2. In the **DHCP Server** section, expand **Advanced**.
3. In **MAC Reservation + Access Control**, double-click in the **Unknown MAC Addresses** line and select **Assign IP** or **Block**, as needed.
   By default, unlisted MAC addresses are assigned an IP address automatically.
4. In **MAC Reservation + Access Control**, select **Create New**.
5. Enter a MAC address In the **MAC** field.
6. In **IP or Action**, select one of:
   - **Reserve IP** — enter the IP address that is always assigned to this MAC address.
   - **Assign IP —** an IP address is assigned to this MAC address automatically.
   - **Block** — This MAC address will not be assigned an IP address.

7. Repeat steps 4 through 6 for each additional MAC address that you want to add.
8. Select **OK**.

To configure a MAC filter - CLI

1. Enter
```
config system dhcp server
show
```
2. Find the entry where `interface` is your WiFi interface. Edit that entry and configure the MAC filter. In this example, the MAC address 11:11:11:11:11:11will be excluded. Unlisted MAC addresses will be assigned an IP address automatically.
```
edit 3
   config reserved-address
      edit 1
         set action block
         set mac 11:11:11:11:11:11
      end
   set mac-acl-default-action assign
end
```

Limiting the number of clients

You might want to prevent overloading of your access point by limiting the number of clients who can associate with it at the same time. Limits can be applied per SSID, per AP, or per radio.

To limit the number of clients per SSID - GUI

1. Go to **WiFI Controller > WiFi Network > SSID** and edit your SSID.
2. Turn on **Maximum Clients** and enter the maximum number of clients in **Limit Concurrent WiFi Clients**.

To limit the number of clients per AP- CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
   edit "FAP221C-default"
      set max-clients 30
   end
```

To limit the number of clients per radio - CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
   edit "FAP221C-default"
      config radio-1
         set max-clients 10
      end
      config radio-2
         set max-clients 30
      end
   end
```

Multicast enhancement

FortiOS can translate multicast traffic into unicast traffic to send to clients, maintaining its own multicast client through IGMP snooping. You can configure this in the CLI:

```
config wireless-controller vap
   edit example_wlan
      set multicast-enhance enable
      set me-disable-thresh 32
   end
```

If the number of clients on the SSID is larger than `me-disable-thresh`, multicast enhancement is disabled.

Dynamic VLAN assignment

You can assign each individual user to a VLAN based on information stored in the RADIUS authentication server. If the user's RADIUS record does not specify a VLAN ID, the user is assigned to the default VLAN for the SSID.

The RADIUS user attributes used for the VLAN ID assignment are:

IETF 64 (Tunnel Type)—Set this to VLAN.

IETF 65 (Tunnel Medium Type)—Set this to 802

IETF 81 (Tunnel Private Group ID)—Set this to the VLAN ID.

To configure dynamic VLAN assignment, you need to:

1. Configure access to the RADIUS server.
2. Create the SSID and enable dynamic VLAN assignment.
3. Create a FortiAP Profile and add the local bridge mode SSID to it.
4. Create the VLAN interfaces and their DHCP servers.
5. Create security policies to allow communication from the VLAN interfaces to the Internet.
6. Authorize the FortiAP unit and assign the FortiAP Profile to it.

To configure access to the RADIUS server

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter a **Name**, the name or IP address in **Primary Server IP/Name**, and the server secret in **Primary Server Secret**.
3. Select **OK**.

To create the dynamic VLAN SSID

1. Go to **WiFi Controller > WiFi Network > SSID**, select Create New and enter:

Name	An identifier, such as dynamic_vlan_ssid.
Traffic Mode	Local bridge or Tunnel, as needed.
SSID	An identifier, such as DYNSSID.
Security Mode	WPA2 Enterprise
Authentication	RADIUS Server. Select the RADIUS server that you configured.

2. Select **OK**.
3. Enable dynamic VLAN in the CLI. Optionally, you can also assign a VLAN ID to set the default VLAN for users without a VLAN assignment.

```
config wireless-controller vap
   edit dynamic_vlan_ssid
      set dynamic-vlan enable
      set vlanid 10
   end
```

To create the FortiAP profile for the dynamic VLAN SSID

1. Go to **WiFi Controller > WiFi Network > FortiAP Profiles**, select Create New and enter:

Name	A name for the profile, such as dyn_vlan_profile.
Platform	The FortiAP model you are using. If you use more than one model of FortiAP, you will need a FortiAP Profile for each model.
Radio 1 and Radio 2	
SSID	Select the SSID you created (example dynamic_vlan_ssid). Do not add other SSIDs.

2. Adjust other radio settings as needed.
3. Select **OK**.

To create the VLAN interfaces

1. Go to **System > Network > Interfaces** and select **Create New**.
2. Enter:

Name	A name for the VLAN interface, such as VLAN100.
Interface	The physical interface associated with the VLAN interface.
VLAN ID	The numeric VLAN ID, for example 100.
Addressing mode	Select Manual and enter the IP address / Network Mask for the virtual interface.
DHCP Server	Enable and then select Create New to create an address range.

3. Select **OK**.
4. Repeat the preceding steps to create other VLANs as needed.

Security policies determine which VLANs can communicate with which other interfaces. These are the simple Firewall Address policy without authentication. Users are assigned to the appropriate VLAN when they authenticate.

To connect and authorize the FortiAP unit

1. Connect the FortiAP unit to the FortiGate unit.
2. Go to **WiFi Controller > Managed Access Points > Managed AP**.

3. When the FortiAP unit is listed, double-click the entry to edit it.
4. In **FortiAP Profile**, select the FortiAP Profile that you created.
5. Select **Authorize**.
6. Select **OK**.

Configuring user authentication

You can perform user authentication when the wireless client joins the wireless network and when the wireless user communicates with another network through a firewall policy. WEP and WPA-Personal security rely on legitimate users knowing the correct key or passphrase for the wireless network. The more users you have, the more likely it is that the key or passphrase will become known to unauthorized people. WPA-Enterprise and captive portal security provide separate credentials for each user. User accounts can be managed through FortiGate user groups or an external RADIUS authentication server.

WPA2 Enterprise authentication

Enterprise authentication can be based on the local FortiGate user database or on a remote RADIUS server. Local authentication is essentially the same for WiFi users as it is for wired users, except that authentication for WiFi users occurs when they associate their device with the AP. Therefore, enterprise authentication must be configured in the SSID. WiFi users can belong to user groups just the same as wired users and security policies will determine which network services they can access.

If your WiFi network uses WPA2 Enterprise authentication verified by a RADIUS server, you need to configure the FortiGate unit to connect to that RADIUS server.

Configuring connection to a RADIUS server - web-based manager

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
   This name is used in FortiGate configurations. It is not the actual name of the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
   edit exampleRADIUS
      set auth-type auto
      set server 10.11.102.100
      set secret aoewmntiasf
   end
```

To implement WPA2 Enterprise security, you select this server in the SSID security settings. See Configuring user authentication on page 830.

To use the RADIUS server for authentication, you can create individual FortiGate user accounts that specify the authentication server instead of a password, and you then add those accounts to a user group. Or, you can add the authentication server to a FortiGate user group, making all accounts on that server members of the user group.

Creating a wireless user group

Most wireless networks require authenticated access. To enable creation of firewall policies specific to WiFi users, you should create at least one WiFi user group. You can add or remove users later. There are two types of user group to consider:

- A Firewall user group can contain user accounts stored on the FortiGate unit or external authentication servers such as RADIUS that contain and verify user credentials.
- A Fortinet Single Sign-On (FSSO) user group is used for integration with Windows Active Directory or Novell eDirectory. The group can contain Windows or Novell user groups who will be permitted access to the wireless LAN.

WiFi Single Sign-On (WSSO) authentication

WSSO is RADIUS-based authentication that passes the user's user group memberships to the FortiGate. For each user, the RADIUS server must provide user group information in the Fortinet-Group-Name attribute. This information is stored in the server's database. After the user authenticates, security policies provide access to network services based on user groups.

1. Configure the RADIUS server to return the Fortinet-Group-Name attribute for each user.
2. Configure the FortiGate to access the RADIUS server, as described in WPA2 Enterprise authentication on page 830.
3. Create firewall user groups on the FortiGate with the same names as the user groups listed in the RADIUS database. Leave the groups empty.
4. In the SSID choose WPA2-Enterprise authentication. In the **Authentication** field, select **RADIUS Server** and choose the RADIUS server that you configured.
5. Create security policies as needed, using user groups (**Source User(s)** field) to control access.

When a user authenticates by WSSO, the firewall monitor (**User & Device > Monitor > Firewall**) shows the authentication method as WSSO.

MAC-based authentication

Wireless clients can also be supplementally authenticated by MAC address. A RADIUS server stores the allowed MAC address for each client and the wireless controller checks the MAC address independently of other authentication methods.

MAC-based authentication must be configured in the CLI. In the following example, MAC-based authentication is added to an existing access point “vap1” to use RADIUS server hq_radius (configured on the FortiGate):

```
config wireless-controller vap
   edit vap1
      set radius-mac-auth enable
      set radius-mac-auth-server hq_radius
   end
```

Authenticating guest WiFi users

The FortiOS Guest Management feature enables you to easily add guest accounts to your FortiGate unit. These accounts are authenticate guest WiFi users for temporary access to a WiFi network managed by a FortiGate unit. To implement guest access, you need to

1. Go to **User & Device > User > User Groups** and create one or more guest user groups.
2. Go to **User & Device > User > Guest Management** to create guest accounts. You can print the guest account credentials or send them to the user as an email or SMS message.

3. Go to **WiFi Controller > WiFi Network > SSID** and configure your WiFi SSID to use captive portal authentication. Select the guest user group(s) that you created.

Guest users can log into the WiFi captive portal with their guest account credentials until the account expires. For more detailed information about creating guest accounts, see “Managing Guest Access” in the Authentication chapter of the FortiOS Handbook.

Configuring firewall policies for the SSID

For users on the WiFi LAN to communicate with other networks, firewall policies are required. This section describes creating a WiFi network to Internet policy.

Before you create firewall policies, you need to define any firewall addresses you will need.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Name	Enter a name for the address, wifi_net for example.
Type	Select **Subnet.**
Subnet / IP Range	Enter the subnet address, 10.10.110.0/24 for example.
Interface	Select the interface where this address is used, e.g., example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
   edit "wifi_net"
      set associated-interface "example_wifi"
      set subnet 10.10.110.0 255.255.255.0
   end
```

To create a firewall policy - web-based manager

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. In **Incoming Interface**, select the wireless interface.
3. In **Source Address**, select the address of your WiFi network, wifi_net for example.
4. In **Outgoing Interface**, select the Internet interface, for example, **port1**.
5. In **Destination Address**, select **All**.
6. In **Service**, select ALL, or select the particular services that you want to allow, and then select the right arrow button to move the service to the **Selected Services** list.
7. In **Schedule**, select **always**, unless you want to define a schedule for limited hours.
8. In **Action**, select ACCEPT.
9. Select **Enable NAT**.
10. Optionally, set up UTM features for wireless users.
11. Select **OK**.

To create a firewall policy - CLI

```
config firewall policy
   edit 0
      set srcintf "example_wifi"
      set dstintf "port1"
      set srcaddr "wifi_net"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
      set nat enable
   end
```

Configuring the built-in access point on a FortiWiFi unit

Both FortiGate and FortiWiFi units have the WiFi controller feature. If you configure a WiFi network on a FortiWiFi unit, you can also use the built-in wireless capabilities in your WiFi network as one of the access points.

If Virtual Domains are enabled, you must select the VDOM to which the built-in access point belongs. You do this in the CLI. For example:

```
config wireless-controller global
   set local-radio-vdom vdom1
end
```

To configure the FortiWiFi unit's built-in WiFi access point

1. Go to **WiFi Controller > Managed Access Points > Local WiFi Radio**.
2. Make sure that **Enable WiFi Radio** is selected.
3. In **SSID**, if you do not want this AP to carry all SSIDs, select **Select SSIDs** and then select the required SSIDs.
4. Optionally, adjust the **TX Power** slider.
   If you have selected your location correctly (see Configuring the built-in access point on a FortiWiFi unit on page 833), the 100% setting corresponds to the maximum power allowed in your region.
5. If you do not want the built-in WiFi radio to be used for rogue scanning, select **Do not participate in Rogue AP scanning**.
6. Select **OK**.

If you want to connect external APs, such as FortiAP units, see the next chapter, Access point deployment.

Access point deployment

This chapter describes how to configure access points for your wireless network.

Overview
Network topology for managed APs
Discovering and authorizing APs
Advanced WiFi controller discovery
Wireless client load balancing for high-density deployments
LAN port options
Preventing IP fragmentation of packets in CAPWAP tunnels

Overview

FortiAP units discover WiFi controllers. The administrator of the WiFi controller authorizes the FortiAP units that the controller will manage.

In most cases, FortiAP units can find WiFi controllers through the wired Ethernet without any special configuration. Review the following section, Access point deployment on page 834, to make sure that your method of connecting the FortiAP unit to the WiFi controller is valid. Then, you are ready to follow the procedures in Access point deployment on page 834.

If your FortiAP units are unable to find the WiFi controller, refer to Access point deployment on page 834 for detailed information about the FortiAP unit's controller discovery methods and how you can configure them.

Network topology for managed APs

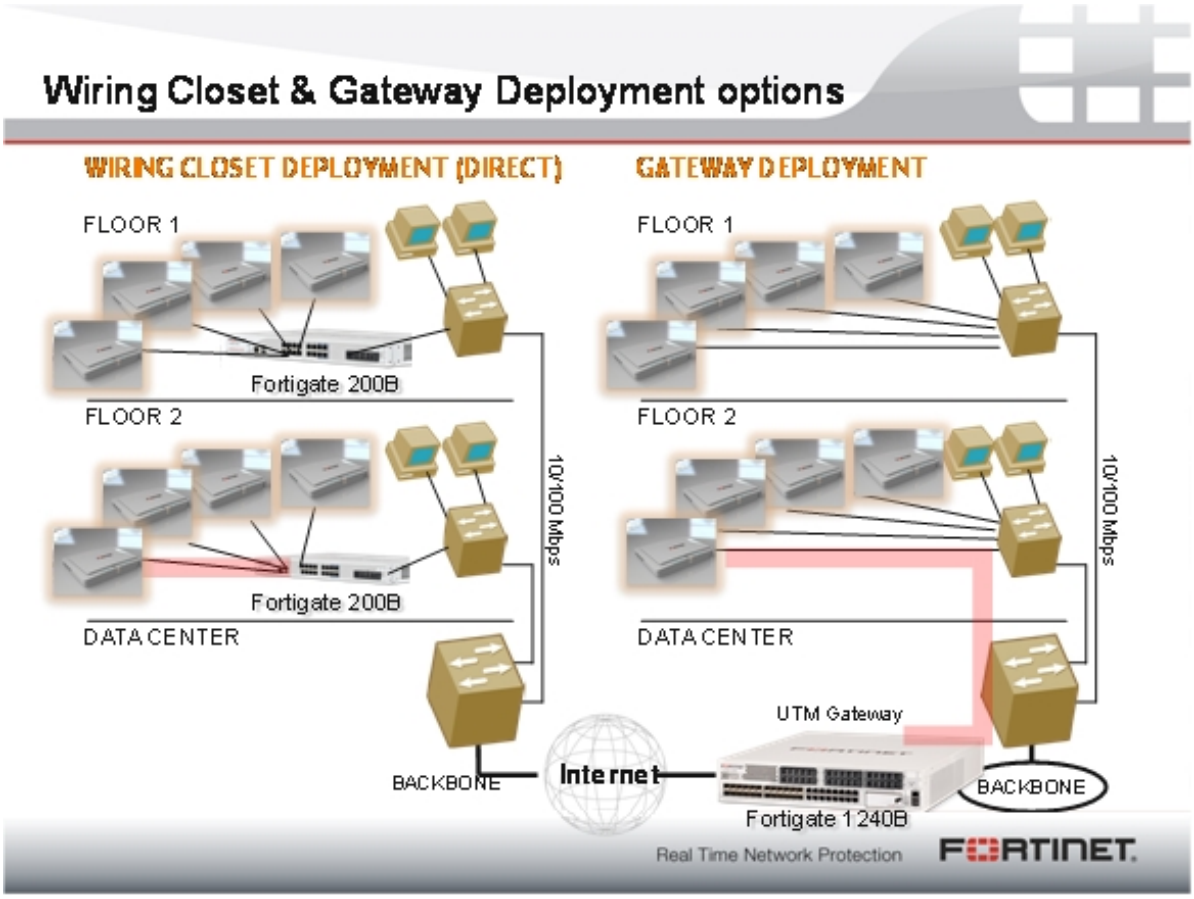
The FortiAP unit can be connected to the FortiGate unit in any of the following ways:

Direct connection: The FortiAP unit is directly connected to the FortiGate unit with no switches between them. This configuration is common for locations where the number of FortiAP's matches up with the number of 'internal' ports available on the FortiGate. In this configuration the FortiAP unit requests an IP address from the FortiGate unit, enters discovery mode and should quickly find the FortiGate WiFi controller. This is also known as a wirecloset deployment. See "Wirecloset and Gateway deployments" below.

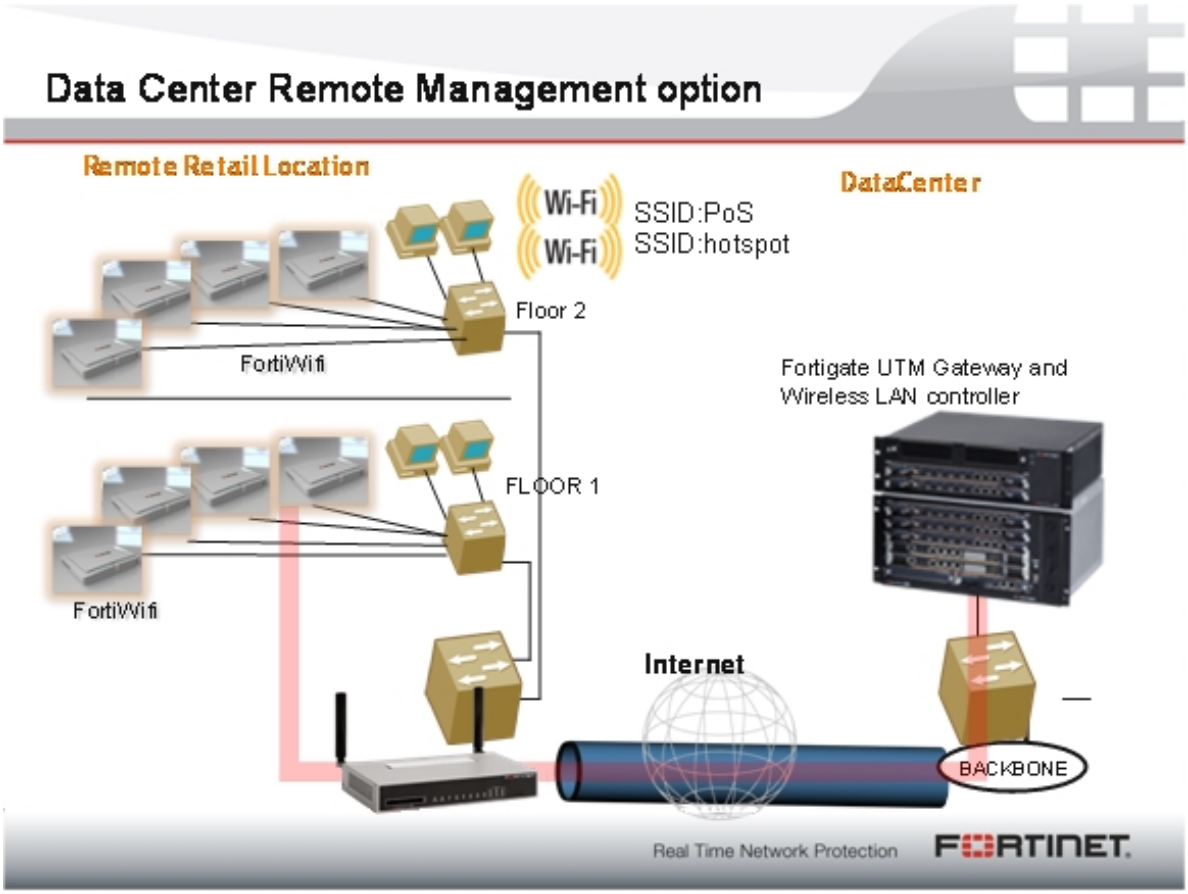
Switched Connection: The FortiAP unit is connected to the FortiGate WiFi controller by an Ethernet switch operating in L2 switching mode or L3 routing mode. There must be a routable path between the FortiAP unit and the FortiGate unit and ports 5246 and 5247 must be open. This is also known as a gateway deployment. See Wirecloset and Gateway deployments below.

Connection over WAN: The FortiGate WiFi controller is off-premises and connected by a VPN tunnel to a local FortiGate. In this method of connectivity its best to configure each FortiAP with the static IP address of the WiFi controller. Each FortiAP can be configured with three WiFi controller IP addresses for redundant failover. This is also known as a datacenter remote management deployment. See Remote deployment below.

Wirecloset and Gateway deployments



Remote deployment



Discovering and authorizing APs

After you prepare your FortiGate unit, you can connect your APs to discover them using the discovery methods described earlier. To prepare the FortiGate unit, you need to

- Configure the network interface to which the AP will connect.
- Configure DHCP service on the interface to which the AP will connect.
- Optionally, preauthorize FortiAP units. They will begin to function when connected.
- Connect the AP units and let the FortiGate unit discover them.
- Enable each discovered AP and configure it or assign it to an AP profile.

Configuring the network interface for the AP unit

The interface to which you connect your wireless access point needs an IP address. No administrative access, DNS Query service or authentication should be enabled.

To configure the interface for the AP unit - web-based manager

1. Go to **System > Network > Interfaces** and edit the interface to which the AP unit connects.
2. Set **Addressing Mode** to **Dedicate to Extension Device.**
3. Enter the IP address and netmask to use.
   This FortiGate unit automatically configures a DHCP server on the interface that will assign the remaining higher addresses up to .254 to FortiAP units. For example, if the IP address is 10.10.1.100, the FortiAP units will be assigned 10.10.1.101 to 10.10.1.254. To maximize the available addresses, use the .1 address for the interface: 10.10.1.1, for example.
4. Select **OK**.

To configure the interface for the AP unit - CLI

In the CLI, you must configure the interface IP address and DHCP server separately.

```
config system interface
   edit port3
      set mode static
      set ip 10.10.70.1 255.255.255.0
   end
config system dhcp server
   edit 0
      set interface "dmz"
      config ip-range
         edit 1
            set end-ip 10.10.70.254
            set start-ip 10.10.70.2
         end
      set netmask 255.255.255.0
      set vci-match enable
      set vci-string "FortiAP"
   end
```

The optional `vci-match` and `vci-string` fields ensure that the DHCP server will provide IP addresses only to FortiAP units.

Pre-authorizing a FortiAP unit

If you enter the FortiAP unit information in advance, it is authorized and will begin to function when it is connected.

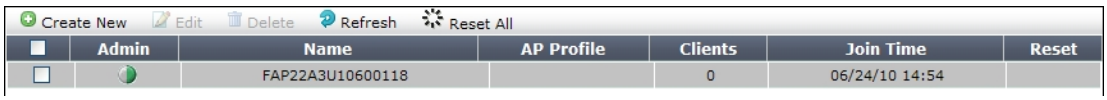
To pre-authorize a FortiAP unit

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAPs** and select **Create New**.
   On some models the **WiFi Controller** menu is called **WiFi & Switch Controller**.
2. Enter the **Serial Number** of the FortiAP unit.
3. Configure the **Wireless Settings** as required.
4. Select **OK**.

Enabling and configuring a discovered AP

Within two minutes of connecting the AP unit to the FortiGate unit, the discovered unit should be listed on **WiFi Controller > Managed Access Points > Managed FortiAP** page.

Discovered access point unit



When you authorize (enable) a FortiAP unit, it is configured by default to use the default FortiAP profile (determined by model). You can create and select a different profile if needed. The FortiAP Profile defines the entire configuration for the AP.

To add and configure the discovered AP unit - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAP**.
   This configuration also applies to local WiFi radio on FortiWiFi models.
2. Select the FortiAP unit from the list and edit it.
3. Optionally, enter a **Name**. Otherwise, the unit will be identified by serial number.
4. Select **Authorize**.
5. Select a **FortiAP Profile**.
6. If you want to override the FortiAP profile, select **Override Settings** and adjust the following:

Enable WiFi Radio	This must be selected to enable operation of this AP.
SSID	**Automatically Inherit all SSIDs** — AP will carry all WiFi networks. **Select SSIDs** — select individual SSIDs for this AP to carry.
Auto TX Power Control	If you enable automatic transmitter power control, adjust TX Power Low and TX Power High to set the power range.
Tx Power	If you are not using automatic power control, adjust AP transmitter power. The 100% setting is the maximum permitted in your country. See Configuring a WiFi LAN on page 815.
Do not participate in Rogue AP scanning	Select this option if scanning adversely affects WiFi traffic.

7. Select **OK**.

The physical access point is now added to the system. If the rest of the configuration is complete, it should be possible to connect to the wireless network through the AP.

To add the discovered AP unit - CLI

First get a list of the discovered access point unit serial numbers:

```
get wireless-controller wtp
```

Add a discovered unit and associate it with AP-profile1, for example:

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set admin enable
    set wtp-profile AP-profile1
  end
```

To use the default profile, leave the `wtp-profile` field unset.

To view the status of the added AP unit

```
config wireless-controller wtp
  edit FAP22A3U10600118
  get
```

The `join-time` field should show a time, not “N/A”. See the preceding web-based manager procedure for more information.

Assigning the same profile to multiple FortiAP units

The same profile can now be applied to multiple managed FortiAP units at the same time. To do this, do the following:

1. Go to **WiFi Controller** > **Managed Access Points** > **Managed FortiAPs** to view the AP list.
2. Select all FortiAP units you wish to apply the profile to.
3. Right click on one of the selected FortiAPs and select **Assign Profile**.
4. Choose the profile you wish to apply.

Connecting to the FortiAP CLI

The FortiAP unit has a CLI through which some configuration options can be set. You can access the CLI using Telnet.

To access the FortiAP unit CLI through the FortiAP Ethernet port

1. Connect your computer to the FortiAP Ethernet interface, either directly with a cross-over cable or through a separate switch or hub.
2. Change your computer’s IP address to 192.168.1.3
3. Telnet to IP address 192.168.1.2.
   Ensure that FortiAP is in a private network with no DHCP server for the static IP address to be accessible.
4. Login with user name admin and no password.
5. Enter commands as needed.
6. Optionally, use the `passwd` command to assign an administrative password for better security.
7. Save the configuration by entering the following command:
   ```
   cfg -c .
   ```
8. Unplug the FortiAP and then plug it back in, in order for the configuration to take effect

To access the FortiAP unit CLI through the FortiGate unit

1. Connect the FortiAP unit to the FortiGate network interface that has been configured for FortiAP units.
2. Use the FortiGate CLI `execute telnet` command to access the FortiAP. For example, if the FortiAP unit IP address is 192.168.1.2, enter:
   ```
   execute telnet 192.168.1.2
   ```
3. At the FortiAP login prompt, enter `admin`. When you are finished using the FortiAP CLI, enter `exit`.

When a WiFi controller has taken control of the FortiAP unit, Telnet access to the FortiAP unit’s CLI is no longer available.

Checking and updating FortiAP unit firmware

You can view and update the FortiAP unit's firmware from the FortiGate unit that acts as its WiFi controller.

Checking the FortiAP unit firmware version

Go to **WiFi Controller > Managed Access Points > Managed FortiAP** to view the list of FortiAP units that the FortiGate unit can manage. The **OS Version** column shows the current firmware version running on each AP.

Updating FortiAP firmware from the FortiGate unit

You can update the FortiAP firmware using either the web-based manager or the CLI. Only the CLI method can update all FortiAP units at once.

To update FortiAP unit firmware - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAP**.
2. Select the FortiAP unit from the list and edit it.
3. In **FortiAP OS Version**, select **Upgrade from File**.
4. Select **Browse** and locate the firmware upgrade file.
5. Select **OK**.
6. When the upgrade process completes, select **OK**.
   The FortiAP unit restarts.

To update FortiAP unit firmware - CLI

1. Upload the FortiAP image to the FortiGate unit.
   For example, the Firmware file is FAP_22A_v4.3.0_b0212_fortinet.out and the server IP address is 192.168.0.100.
   ```
   execute wireless-controller upload-wtp-image tftp FAP_22A_v4.3.0_b0212_fortinet.out
       192.168.0.100
   ```
   If your server is FTP, change `tftp` to `ftp`, and if necessary add your user name and password at the end of the command.
2. Verify that the image is uploaded:
   ```
   execute wireless-controller list-wtp-image
   ```
3. Upgrade the FortiAP units:
   ```
   exec wireless-controller reset-wtp all
   ```
   If you want to upgrade only one FortiAP unit, enter its serial number instead of `all`.

Updating FortiAP firmware from the FortiAP unit

You can connect to a FortiAP unit's internal CLI to update its firmware from a TFTP server on the same network. This method does not require access to the wireless controller.

1. Place the FortiAP firmware image on a TFTP server on your computer.
2. Connect the FortiAP unit to a separate private switch or hub or directly connect to your computer via a cross-over cable.
3. Change your computer's IP address to 192.168.1.3.

4. Telnet to IP address 192.168.1.2.
   This IP address is overwritten if the FortiAP is connected to a DHCP environment. Ensure that the FortiAP unit is in a private network with no DHCP server.
5. Login with the username “admin” and no password.
6. Enter the following command.
   For example, the FortiAP image file name is FAP_22A_v4.3.0_b0212_fortinet.out.

```
restore FAP_22A_v4.3.0_b0212_fortinet.out 192.168.1.3
```

Advanced WiFi controller discovery

A FortiAP unit can use any of four methods to locate a controller. By default, FortiAP units cycle through all four of the discovery methods. In most cases there is no need to make configuration changes on the FortiAP unit.

There are exceptions. The following section describes the WiFi controller discovery methods in more detail and provides information about configuration changes you might need to make so that discovery will work.

Controller discovery methods

There are four methods that a FortiAP unit can use to discover a WiFi controller.

Static IP configuration

If FortiAP and the controller are not in the same subnet, broadcast and multicast packets cannot reach the controller. The admin can specify the controller’s static IP on the AP unit. The AP unit sends a discovery request message in unicast to the controller. Routing must be properly configured in both directions.

To specify the controller’s IP address on a FortiAP unit

```
cfg -a AC_IPADDR_1="192.168.0.100"
```

By default, the FortiAP unit receives its IP address, netmask, and gateway address by DHCP. If you prefer, you can assign these statically.

To assign a static IP address to the FortiAP unit

```
cfg -a ADDR_MODE=STATIC
cfg -a AP_IPADDR="192.168.0.100"
cfg -a AP_NETMASK="255.255.255.0"
cfg -a IPGW=192.168.0.1
cfg -c
```

For information about connecting to the FortiAP CLI, see Advanced WiFi controller discovery on page 841.

Broadcast request

The AP unit broadcasts a discovery request message to the network and the controller replies. The AP and the controller must be in the same broadcast domain. No configuration adjustments are required.

Multicast request

The AP unit sends a multicast discovery request and the controller replies with a unicast discovery response message. The AP and the controller do not need to be in the same broadcast domain if multicast routing is properly configured.

The default multicast destination address is 224.0.1.140. It can be changed through the CLI. The address must be same on the controller and AP.

To change the multicast address on the controller

```
config wireless-controller global
   set discovery-mc-addr 224.0.1.250
end
```

To change the multicast address on a FortiAP unit

```
cfg -a AC_DISCOVERY_MC_ADDR="224.0.1.250"
```

For information about connecting to the FortiAP CLI, see Advanced WiFi controller discovery on page 841.

DHCP

If you use DHCP to assign an IP address to your FortiAP unit, you can also provide the WiFi controller IP address at the same time. This is useful if the AP is located remotely from the WiFi controller and other discovery techniques will not work.

When you configure the DHCP server, configure Option 138 to specify the WiFi controller IP address. You need to convert the address into hexadecimal. Convert each octet value separately from left to right and concatenate them. For example, 192.168.0.1 converts to C0A80001.

If Option 138 is used for some other purpose on your network, you can use a different option number if you configure the AP units to match.

To change the FortiAP DHCP option code

To use option code 139 for example, enter

```
cfg -a AC_DISCOVERY_DHCP_OPTION_CODE=139
```

For information about connecting to the FortiAP CLI, see Advanced WiFi controller discovery on page 841.

Wireless client load balancing for high-density deployments

Wireless load balancing allows your wireless network to distribute wireless traffic more efficiently among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- Access Point Hand-off - the wireless controller signals a client to switch to another access point.
- Frequency Hand-off - the wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Load balancing is not applied to roaming clients.

Access point hand-off

Access point handoff wireless load balancing involves the following:

- If the load on an access point (ap1) exceeds a threshold (of for example, 30 clients) then the client with the weakest signal will be signaled by wireless controller to drop off and join another nearby access point (ap2).

- When one or more access points are overloaded (for example, more than 30 clients) and a new client attempts to join a wireless network, the wireless controller selects the least busy access point that is closest to the new client and this access point is the one that responds to the client and the one that the client joins.

Frequency hand-off or band-steering

Encouraging clients to use the 5GHz WiFi band if possible enables those clients to benefit from faster interference-free 5GHz communication. The remaining 2.4GHz clients benefit from reduced interference.

The WiFi controller probes clients to determine their WiFi band capability. It also records the RSSI (signal strength) for each client on each band.

If a new client attempts to join the network, the controller looks up that client's MAC address in its wireless device table and determines if it's a dual band device. If it is not a dual band device, then its allowed to join. If it is a dual band device, then its RSSI on 5GHz is used to determine whether the device is close enough to an access point to benefit from movement to 5GHz frequency.

If both conditions of 1) dual band device and 2) RSSI value is strong, then the wireless controller does not reply to the join request of the client. This forces the client to retry a few more times and then timeout and attempt to join the same SSID on 5GHz. Once the Controller see this new request on 5GHz, the RSSI is again measured and the client is allowed to join. If the RSSI is below threshold, then the device table is updated and the controller forces the client to timeout again. A client's second attempt to connect on 2.4GHz will be accepted.

Configuration

From the web-based manager, edit a custom AP profile and select **Frequency Handoff** and **AP Handoff** as required for each radio on the AP.

From the CLI, you configure wireless client load balancing thresholds for each custom AP profile. Enable access point hand-off and frequency hand-off separately for each radio in the custom AP profile.

```
config wireless-controller wtp-profile
   edit new-ap-profile
      set handoff-rssi <rssi_int>
      set handoff-sta-thresh <clients_int>
      config radio-1
         set frequency-handoff {disable | enable}
         set ap-handoff {disable | enable}
      end
      config radio-2
         set frequency-handoff {disable | enable}
         set ap-handoff {disable | enable}
      end
   end
```

Where:

- `handoff-rssi` is the RSSI threshold. Clients with a 5 GHz RSSI threshold over this value are load balanced to the 5GHz frequency band. Default is 25. Range is 20 to 30.
- `handoff-sta-thresh` is the access point handoff threshold. If the access point has more clients than this threshold it is considered busy and clients are changed to another access point. Default is 30, range is 5 to 25.
- `frequency-handoff` enable or disable frequency handoff load balancing for this radio. Disabled by default.
- `ap-handoff` enable or disable access point handoff load balancing for this radio. Disabled by default.

Frequency handoff must be enabled on the 5GHz radio to learn client capability.

LAN port options

Some FortiAP models have one or more ethernet interfaces marked LAN. These ports can provide wired network access. LAN ports are bridged to either the wired WAN interface or to one of the WiFi SSIDs that the FortiAP unit carries.

Bridging a LAN port with an SSID

Bridging a LAN port with a FortiAP SSID combines traffic from both sources to provide a single broadcast domain for wired and wireless users.

In this configuration

- The IP addresses for LAN clients come from the DHCP server that serves the wireless clients.
- Traffic from LAN clients is bridged to the SSID's VLAN. Dynamic VLAN assignment for hosts on the LAN port is not supported.
- Wireless and LAN clients are on the same network and can communicate locally, via the FortiAP.
- Any host connected to the LAN port will be taken as authenticated. RADIUS MAC authentication for hosts on the LAN port is not supported.

For configuration instructions, see LAN port options on page 844.

Bridging a LAN port with the WAN port

Bridging a LAN port with the WAN port enables the FortiAP unit to be used as a hub which is also an access point.

In this configuration

- The IP addresses for LAN clients come from the WAN directly and will typically be in the same range as the AP itself.
- All LAN client traffic is bridged directly to the WAN interface.
- Communication between wireless and LAN clients can only occur if a policy on the FortiGate unit allows it.

For configuration instructions, see LAN port options on page 844.

Configuring FortiAP LAN ports

You can configure FortiAP LAN ports for APs in a FortiAP Profile. A profile applies to APs that are the same model and share the same configuration. If you have multiple models or different configurations, you might need to create several FortiAP Profiles. For an individual AP, it is also possible to override the profile settings.

To configure FortiAP LAN ports in a FortiAP Profile - web-based manager

1. Go to **WiFi Controller > FortiAP Profiles.**
2. Edit the default profile for your FortiAP model or select **Create New**.
3. If you are creating a new profile, enter a **Name** and select the correct **Platform** (model).
4. Select SSIDs.
5. In the **LAN Port** section, set **Mode** to **Bridge to** and select an SSID or **WAN Port** as needed.
   On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually. Enable each port that you want to use and select an SSID or **WAN Port** as needed.
6. Select **OK**.

Be sure to select this profile when you authorize your FortiAP units.

To configure FortiAP LAN ports - CLI

In this example, the default FortiAP-11C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
   edit FAP11C-default
      config lan
         set port-mode bridge-to-ssid
         set port-ssid office
      end
   end
end
```

In this example, the default FortiAP-28C profile is configured to bridge LAN port1 to the office SSID and to bridge the other LAN ports to the WAN port.

```
config wireless-controller wtp-profile
   edit FAP28C-default
      config lan
         set port1-mode bridge-to-ssid
         set port1-ssid office
         set port2-mode bridge-to-wan
         set port3-mode bridge-to-wan
         set port4-mode bridge-to-wan
         set port5-mode bridge-to-wan
         set port6-mode bridge-to-wan
         set port7-mode bridge-to-wan
         set port8-mode bridge-to-wan
      end
   end
```

To configure FortiAP unit LAN ports as a FortiAP Profile override - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAPs**.
   On FortiGate models 100D, 600C, 800C, and 1000C, go to **WiFi & Switch Controller > Managed Devices > Managed FortiAPs**.
2. Select the FortiAP unit from the list and select **Edit**.
3. Select the **FortiAP Profile**, if this has not already been done.
4. Enable **Override Settings**.
5. In the **LAN Port** section, set **Mode** to **Bridge to** and select an SSID or **WAN Port** as needed.
   On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually. Enable each port that you want to use and select an SSID or **WAN Port** as needed.
6. Select **OK**.

To configure FortiAP unit LAN ports as a FortiAP Profile override - CLI

In this example, a FortiAP unit's configuration overrides the FortiAP Profile to bridge the LAN port to the WAN port.

```
config wireless-controller wtp
   edit FAP11C3X13000412
      set wtp-profile FAP11C-default
      set override-profile enable
      config lan
         set port-mode bridge-to-wan
      end
```

```
    end
```

Preventing IP fragmentation of packets in CAPWAP tunnels

A common problem with controller-based WiFi networks is reduced performance due to IP fragmentation of the packets in the CAPWAP tunnel.

Fragmentation can occur because of CAPWAP tunnel overhead increasing packet size. If the original wireless client packets are close to the maximum transmission unit (MTU) size for the network (usually 1500 bytes for Ethernet networks unless jumbo frames are used) the resulting CAPWAP packets may be larger than the MTU, causing the packets to be fragmented. Fragmenting packets can result in data loss, jitter, and decreased throughput.

The FortiOS/FortiAP solution to this problem is to cause wireless clients to send smaller packets to FortiAP devices, resulting in 1500-byte CAPWAP packets and no fragmentation. The following options configure CAPWAP IP fragmentation control:

```
config wireless-controller wtp-profile
   edit new-wtp
      set ip-fragment-preventing tcp-mss-adjust icmp-unreachable
      set tun-mtu-uplink {0 | 576 | 1500}
      set tun-mtu-downlink {0 | 576 | 1500}
   end
end
```

By default, `tcp-mss-adjust` and `icmp-unreachable` are not enabled, and `tun-mtu-uplink` and `tun-mtu-downlink` are set to 0.

To set `tun-mtu-uplink` and `tun-mtu-downlink`, use the default TCP MTU value of 1500. This default configuration prevents packet fragmentation because the FortiAP unit limits the size of TCP packets received from wireless clients so the packets don't have to be fragmented before CAPWAP encapsulation.

The `tcp-mss-adjust` option causes the FortiAP unit to limit the maximum segment size (MSS) of TCP packets sent by wireless clients. The FortiAP does this by adding a reduced MSS value to the SYN packets sent by the FortiAP unit when negotiating with a wireless client to establish a session. This results in the wireless client sending packets that are smaller than the `tun-mtu-uplink` setting, so that when the CAPWAP headers are added, the CAPWAP packets have an MTU that matches the `tun-mtu-uplink` size.

The `icmp-unreachable` option affects all traffic (UDP and TCP) between wireless clients and the FortiAP unit. This option causes the FortiAP unit to drop packets that have the "Don't Fragment" bit set in their IP header and that are large enough to cause fragmentation and then send an ICMP packet -- type 3 "ICMP Destination unreachable" with code 4 "Fragmentation Needed and Don't Fragment was Set" back to the wireless controller. This should cause the wireless client to send smaller TCP and UDP packets.

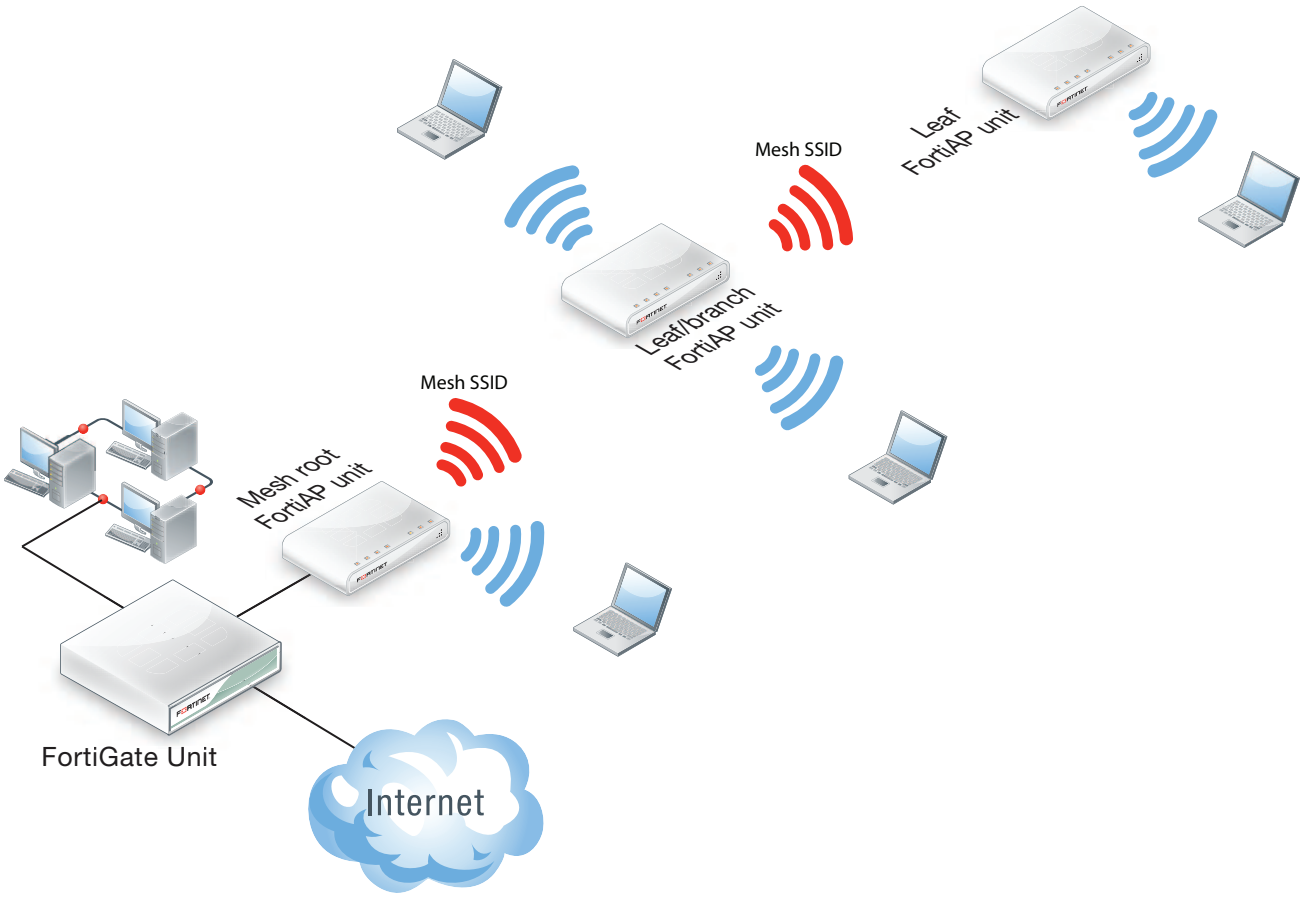
Wireless Mesh

The access points of a WiFi network are usually connected to the WiFi controller through Ethernet wiring. A wireless mesh eliminates the need for Ethernet wiring by connecting WiFi access points to the controller by radio. This is useful where installation of Ethernet wiring is impractical.

Overview of Wireless Mesh
Configuring a meshed WiFi network
Configuring a point-to-point bridge

Overview of Wireless Mesh

The figure below shows a wireless mesh topology.



The AP that is connected to the network by Ethernet is called the Mesh Root node. It is configured with an SSID (also called a virtual access point or VAP) dedicated to backhaul communication with the remote FortiAP units. The backhaul SSID carries CAPWAP discovery, configuration, and other communications that would usually be carried on an Ethernet connection. Regular WiFi clients cannot connect to the backhaul SSID. They connect to the regular SSIDs carried on the access points.

The root node can be a FortiAP unit or the built-in AP of a FortiWiFi unit. APs that serve only regular WiFi clients are called Leaf nodes. Leaf APs that also carry the mesh SSID for more distant Leaf nodes are called Leaf/branch nodes.

All access points in a wireless mesh configuration must have at least one of their radios configured to provide mesh backhaul communication. As with wired APs, when mesh APs start up they can be discovered by a FortiGate or FortiWiFi unit WiFi controller and authorized to join the network.

The backhaul SSID delivers the best performance when it is carried on a dedicated radio. On a two-radio FortiAP unit, for example, the 5GHz radio could carry only the backhaul SSID while the 2.4GHz radio carries one or more SSIDs that serve users. Background WiFi scanning is possible in this mode.

The backhaul SSID can also share the same radio with SSIDs that serve users. Performance is reduced because the backhaul and user traffic compete for the available bandwidth. Background WiFi scanning is not available in this mode. One advantage of this mode is that a two-radio AP can offer WiFi coverage on both bands.

The root mesh AP is the AP unit that has a wired Ethernet connection to the WiFi controller. The AP units that are wirelessly linked to the controller over the backhaul SSID are called branch or leaf APs.

Wireless mesh deployment modes

There are two common wireless mesh deployment modes:

Wireless Mesh	Access points are wirelessly connected to a FortiGate or FortiWiFi unit WiFi controller. WiFi users connect to wireless SSIDs in the same way as on non-mesh WiFi networks.
Wireless bridging	Two LAN segments are connected together over a wireless link (the backhaul SSID). On the leaf AP, the Ethernet connection can be used to provide a wired network. Both WiFi and wired users on the leaf AP are connected to the LAN segment to which the root AP is connected.

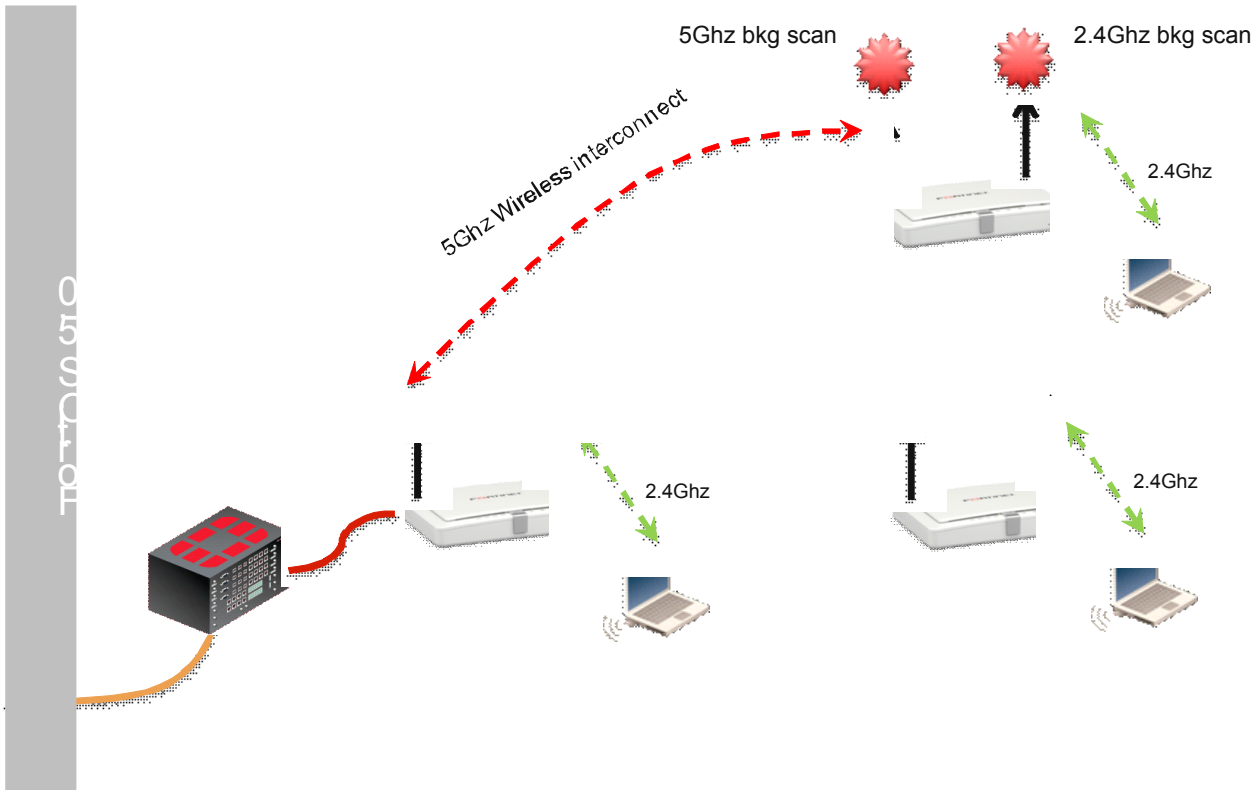
Firmware requirements

All FortiAP units that will be part of the wireless mesh network must be upgraded to FAP firmware version 5.0 build 003. FortiAP-222B units must have their BIOS upgraded to version 400012. The FortiWiFi or FortiGate unit used as the WiFi controller must be running FortiOS 5.0.

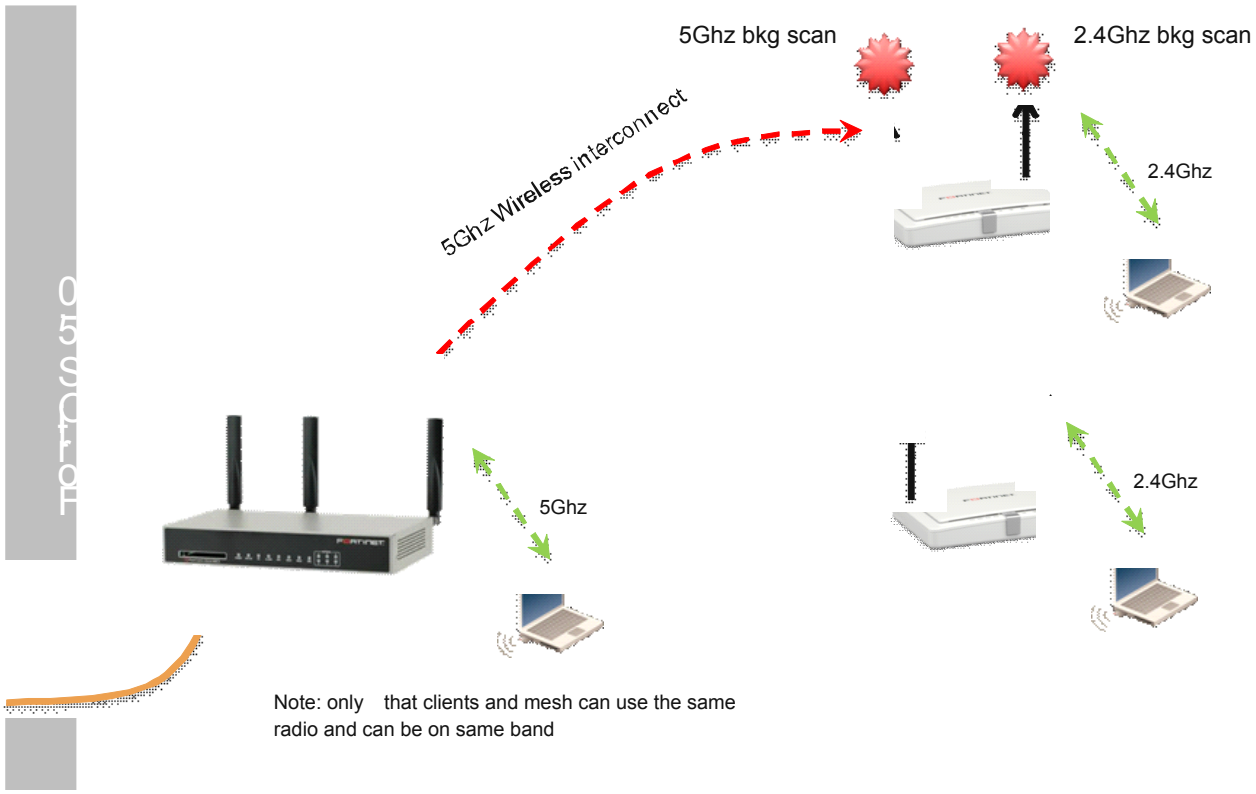
Types of wireless mesh

A WiFi mesh can provide access to widely-distributed clients. The root mesh AP which is directly connected to the WiFi controller can be either a FortiAP unit or the built-in AP of a FortiWiFi unit that is also the WiFi controller.

FortiAP units used as both mesh root AP and leaf AP

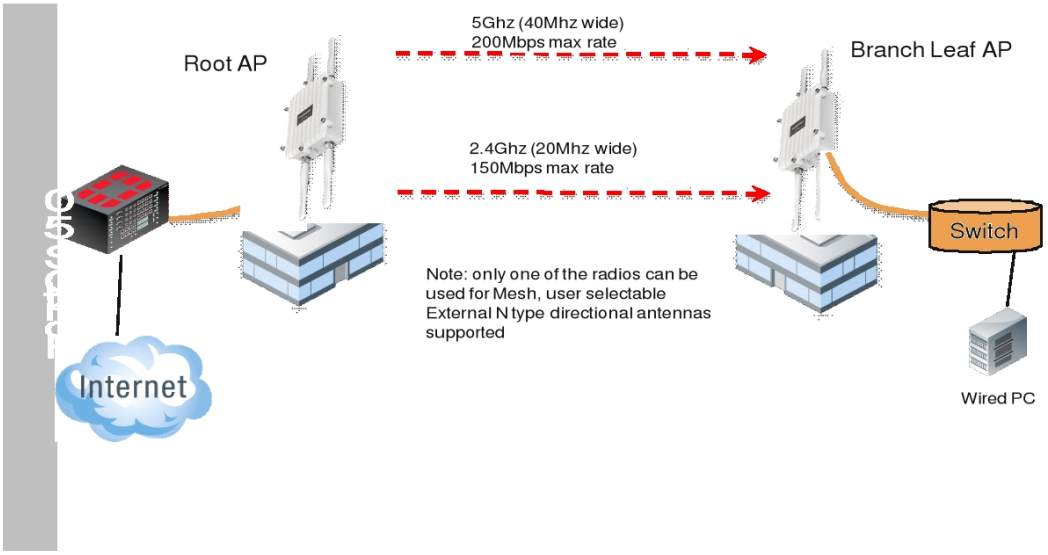


FortiWiFi unit as root mesh AP with FortiAP units as leaf APs



An alternate use of the wireless mesh functionality is as a point-to-point relay. Both wired and WiFi users on the leaf AP side are connected to the LAN segment on the root mesh side.

Point-to-point wireless mesh



Configuring a meshed WiFi network

Each VDOM on the FortiGate unit contains a predefined WiFi mesh interface named wl.mesh and a predefined SSID (which cannot be deleted) named fortinet.mesh.<vdom-name>. You can create additional mesh SSIDs. Create the SSID with **Traffic Mode** set to **Mesh Downlink**.

You need to:

- Create custom AP profiles, if you are not using the automatic AP profile.
- Configure the mesh root AP, either a FortiWiFi unit's Local Radio or a FortiAP unit.
- Configure mesh branch/leaf AP units.
- Authorize the mesh branch/leaf units when they connect to the WiFi Controller.

Creating custom AP profiles

You can apply the automatic AP profile or create one or more custom AP profiles for the mesh root and branch/leaf APs. A custom profile provides more control over which radio channels are used, intrustion protection, load balancing, background rogue AP scanning, and so on. Typically, the custom profiles are configured so that Radio 1 (5GHz) carries the mesh backhaul SSID while Radio 2 (2.4GHz) carries the SSIDs to which users connect.

For more information, see Configuring a WiFi LAN on page 815.

Configuring the mesh root AP

The mesh root AP can be either a FortiWiFi unit's built-in AP or a FortiAP unit.

To enable a FortiWiFi unit's Local Radio as mesh root - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Local WiFi Radio**.
2. Select **Enable WiFi Radio**.
3. In **SSID**, select **Select SSIDs**, then select **fortinet.mesh.root**.
4. Optionally, adjust **TX Power** or select **Auto Tx Power Control**.
5. Select **Apply**.

In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi Controller > WiFI Network > SSID** to change the SSID.

Fortinet also recommends that you create a new preshared key instead of using the default.

To configure a network interface for the FortiAP unit

1. On the FortiGate unit, go to **System > Network > Interfaces**.
2. Select the interface where you will connect the FortiAP unit and edit it.
3. In **Addressing mode**, select **Manual**.

4. In **IP/Network Mask**, enter an IP address and netmask for the interface.
   To maximize the number of addresses available for clients, the interface address should end with 1, for example 192.168.10.1.
5. In **DHCP Server** select **Enable**.
   An **Address Range** is entered automatically. It consists of the subnet address space above the interface address. For example, if the interface IP/mask is 192.168.10.100/24, the DHCP address range is 192.168.10.101 through 192.168.10.254.
6. Select **OK**.

To enable a FortiAP unit as mesh root - web-based manager

1. Connect the root FortiAP unit's Ethernet port to the FortiGate network interface that you configured for it. Connect the FortiAP unit to its power source.
2. Go to **WiFi Controller > Managed Access Points > Managed FortiAP**.
   If the root FortiAP unit is not listed, wait 15 seconds and select **Refresh**. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the root FortiAP unit and try again.
3. Select the discovered FortiAP unit and edit its settings.
4. Select the **FortiAP Profile** to apply.
5. In **State**, select **Authorize**.
6. Select **OK**.

You need to create firewall policies to permit traffic to flow from the network interface where the FortiAP unit is connected to the network interfaces for the Internet and other networks. Enable NAT.

Configuring the mesh branches or leaves

The FortiAP units that will serve as branch/leaf nodes must be preconfigured.

1. Connect to the FortiAP unit web-based manager on its default Ethernet interface IP address, 192.168.1.2.
2. In the **Connectivity** section enter:

Uplink	Mesh
Mesh AP SSID	fortinet.mesh.<vdom-name> For example, for the root domain, fortinet.mesh.root.
Mesh AP Password	Same as Mesh AP SSID.
Ethernet Bridge	Select

3. Select **Apply** and then select **Logout**.

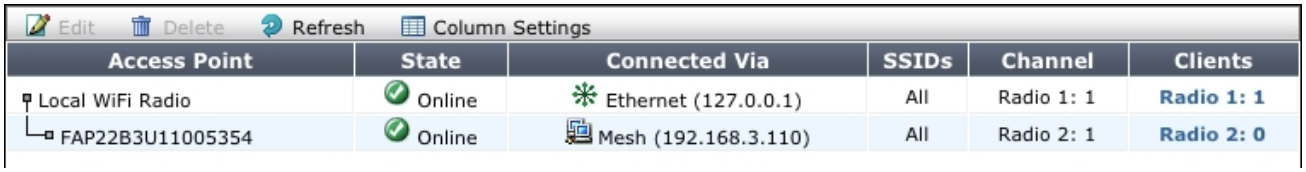
Authorizing mesh branch/leaf APs

The pre-configured branch/leaf FortiAP units will connect themselves wirelessly to the WiFi Controller through the mesh network. You must authorize each unit

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAP**. Periodically select **Refresh** until the FortiAP unit is listed.
   The **State** of the FortiAP unit should be **Waiting for Authorization**.
2. Open the FortiAP entry for editing.
3. Select the **FortiAP Profile** to apply.

4. Select **Authorize**.
5. Select **OK**.
   Initially, the **State** of the FortiAP unit is **Offline**. Periodically select **Refresh** to update the status. Within about two minutes, the state changes to **Online**.

FortiWiFi unit as root mesh with FortiAP unit as branch/leaf node



Viewing the status of the mesh network

Go to **WiFi Controller > Managed Access Points > Managed FortiAP** to view the list of APs. The **Connected Via** field shows **Mesh** for mesh-connected units and lists the IP address to which they connect.

In the FortiAP CLI, you can check the `main ip` field in the output from the command

```
cw_diag -c mesh
```

Configuring a point-to-point bridge

You can create a point-to-point bridge to connect two wired network segments using a WiFi link. The effect is the same as connecting the two network segments to the same wired switch.

You need to:

- Configure a backhaul link and root mesh AP as described in Configuring a point-to-point bridge on page 853.
  Note: The root mesh AP for a point-to-point bridge must be a FortiAP unit, not the internal AP of a FortiWiFi unit.
- Configure bridging on the leaf AP unit.

To configure the leaf AP unit for bridged operation - FortiAP web-based manager

1. With your browser, connect to the FortiAP unit web-based manager.
   You can temporarily connect to the unit's Ethernet port and use its default address: 192.168.1.2.
2. Enter:

Operation Mode	Mesh
Mesh AP SSID	fortinet-ap
Mesh AP Password	fortinet
Ethernet Bridge	Select

3. Select **Apply**.
4. Connect the local wired network to the Ethernet port on the FortiAP unit.
   Users are assigned IP addresses from the DHCP server on the wired network connected to the root mesh AP unit.

To configure a FortiAP unit as a leaf AP - FortiAP CLI

```
cfg -a MESH_AP_SSID=fortinet-ap
cfg -a MESH_AP_PASSWD=fortinet
cfg -a MESH_ETH_BRIDGE=1
cfg -a MESH_AP_TYPE=1
cfg -c
```

Combining WiFi and wired networks with a software switch

Combining WiFi and wired networks with a software switch
FortiAP local bridging (Private Cloud-Managed AP)
Using bridged FortiAPs to increase scalability

Combining WiFi and wired networks with a software switch

A WiFi network can be combined with a wired LAN so that WiFi and wired clients are on the same subnet. This is a convenient configuration for users. Note that software switches are only available if your FortiGate is in Interface mode.

Wireless Mesh features cannot be used in conjunction with this configuration because they enable the FortiAP Local Bridge option.

To create the WiFi and wired LAN configuration, you need to:

- Configure the SSID so that traffic is tunneled to the WiFi controller.
- Configure a software switch interface on the FortiGate unit with the WiFi and internal network interface as members.
- Configure Captive Portal security for the software switch interface.

To configure the SSID - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Enter:

Interface name	A name for the new WiFi interface, `homenet_if` for example.
Traffic Mode	Tunnel to Wireless Controller
SSID	The SSID visible to users, `homenet` for example.
Security Mode **Data Encryption** **Preshared Key**	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi Controller > Managed Access Points > Managed FortiAP,** select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
   The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

To configure the SSID - CLI

This example creates a WiFi interface “homenet_if” with SSID “homenet” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
```

```
    edit "homenet_if"
      set vdom "root"
      set ssid "homenet"
      set security wpa-personal
      set passphrase "Fortinet1"
    end
  config wireless-controller wtp
    edit FAP22B3U11005354
      set admin enable
      set vaps "homenet_if"
    end
```

To configure the FortiGate unit - web-based manager

1. Go to **System > Network > Interfaces** and select **Create New**.
2. Enter:

Interface Name	A name for the new interface, `homenet_nw` for example.
Type	Software Switch
Interface Members	Add homenet_if and the internal network interface.
Addressing Mode	Select Manual and enter an address, for example `172.16.96.32/255.255.255.0`
DHCP Server	Enable and configure an address range for clients.
Security Mode	Select **Captive Portal**. Add the permitted **User Groups**.

3. Select **OK**.

To configure the FortiGate unit - CLI

```
config system interface
  edit homenet_nw
    set ip 172.16.96.32 255.255.255.0
    set type switch
    set security-mode captive-portal
    set security-groups "Guest-group"
  end
config system interface
  edit homenet_nw
    set member "homenet_if" "internal"
  end
```

VLAN configuration

If your environment uses VLAN tagging, you assign the SSID to a specific VLAN in the CLI. For example, to assign the homenet_if interface to VLAN 100, enter:

```
config wireless-controller vap
  edit "homenet_if"
    set vlanid 100
  end
```

Additional configuration

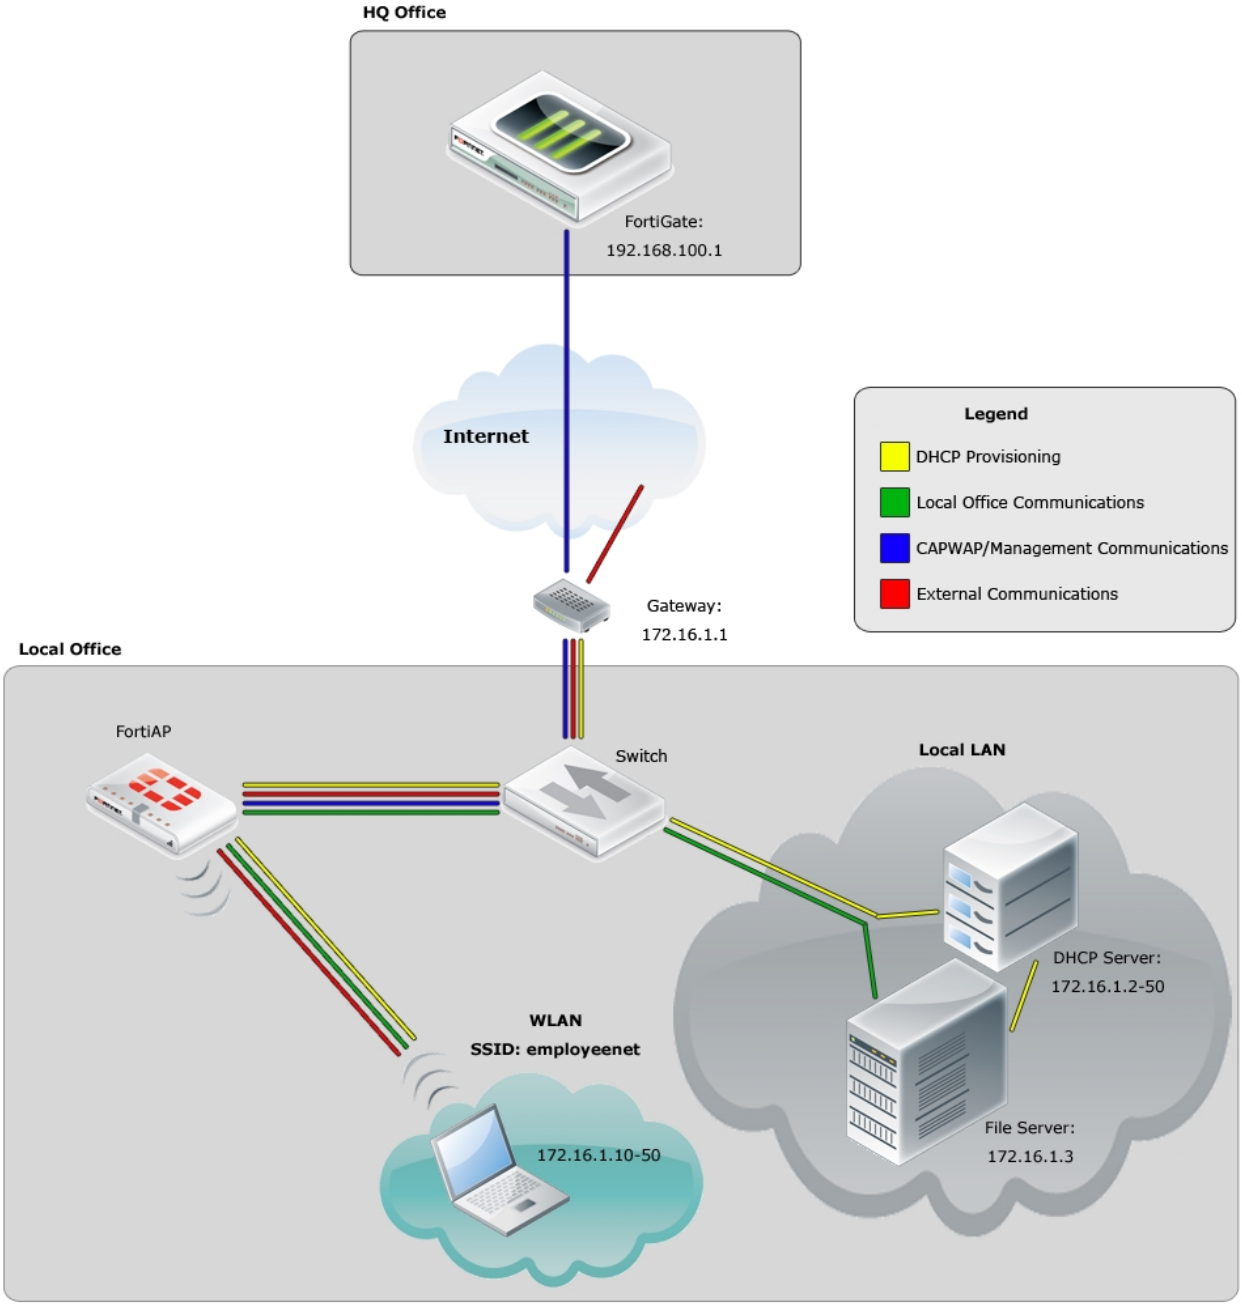
The configuration described above provides communication between WiFi and wired LAN users only. To provide access to other networks, create appropriate firewall policies between the software switch and other interfaces.

FortiAP local bridging (Private Cloud-Managed AP)

A FortiAP unit can provide WiFi access to a LAN, even when the wireless controller is located remotely. This configuration is useful for the following situations:

- Installations where the WiFI controller is remote and most of the traffic is local or uses the local Internet gateway
- Wireless-PCI compliance with remote WiFi controller
- Telecommuting, where the FortiAP unit has the WiFi controller IP address pre-configured and broadcasts the office SSID in the user's home or hotel room. In this case, data is sent in the wireless tunnel across the Internet to the office and you should enable encryption using DTLS.

Remotely-managed FortiAP providing WiFi access to local network



On the remote FortiGate wireless controller, the WiFi SSID is created with the **Bridge with FortiAP Interface** option selected. In this mode, no IP addresses are configured. The FortiAP unit's WiFi and Ethernet interfaces behave as a switch. WiFi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN.

The Local Bridge feature cannot be used in conjunction with Wireless Mesh features.

Block-Intra-SSID Traffic is not available in Bridge mode.

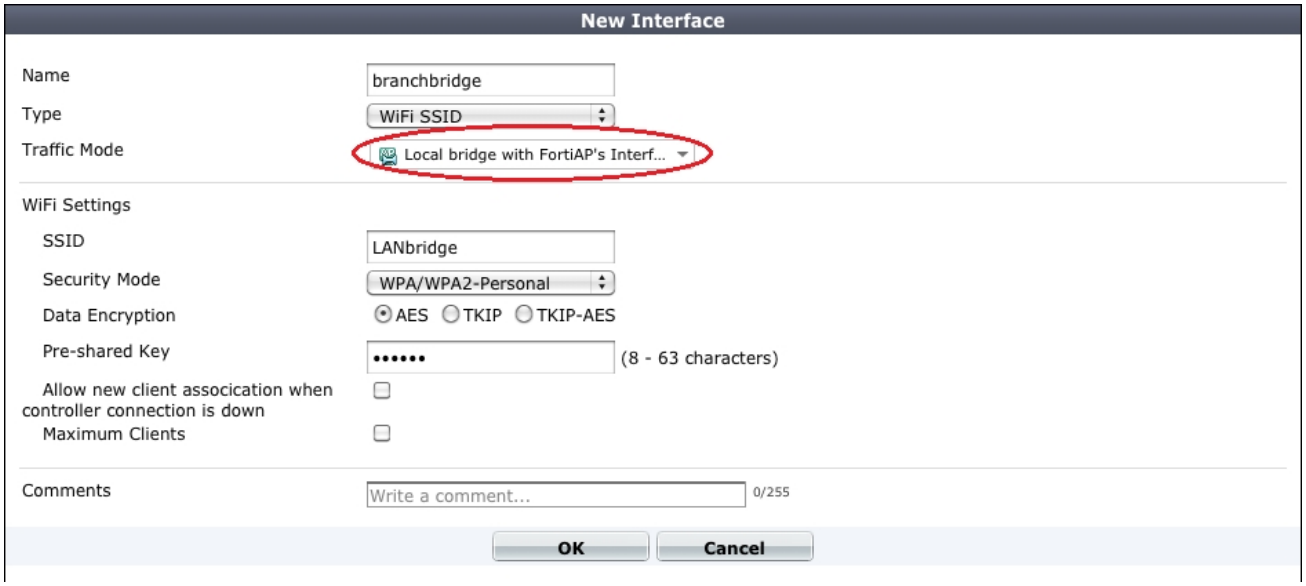
To configure a FortiAP local bridge - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Enter:

Interface name	A name for the new WiFi interface.
Traffic Mode	Local bridge with FortiAP's Interface
SSID	The SSID visible to users.
Security Mode **Data Encryption** **Preshared Key**	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi Controller > Managed Access Points > Managed FortiAP,** select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
   The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

SSID configured for Local Bridge operation



To configure a FortiAP local bridge - CLI

This example creates a WiFi interface “branchbridge” with SSID “LANbridge” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
   edit "branchbridge"
      set vdom "root"
      set ssid "LANbridge"
      set local-bridging enable
      set security wpa-personal
      set passphrase "Fortinet1"
   end
```

```
config wireless-controller wtp
   edit FAP22B3U11005354
      set admin enable
      set vaps "branchbridge"
   end
```

Continued FortiAP operation when WiFi controller connection is down

The wireless controller, or the connection to it, might occasionally become unavailable. During such an outage, clients already associated with a bridge mode FortiAP unit continue to have access to the WiFi and wired networks. Optionally, the FortiAP unit can also continue to authenticate users if the SSID meets these conditions:

- **Traffic Mode** is **Local bridge with FortiAP's Interface**.
  In this mode, the FortiAP unit does not send traffic back to the wireless controller.
- **Security Mode** is **WPA2 Personal**.
  These modes do not require the user database. In WPA2 Personal authentication, all clients use the same pre-shared key which is known to the FortiAP unit.
- **Allow New WiFi Client Connections When Controller is down** is enabled.
  This field is available only if the other conditions have been met.

The "LANbridge" SSID example would be configured like this in the CLI:

```
config wireless-controller vap
   edit "branchbridge"
      set vdom "root"
      set ssid "LANbridge"
      set local-bridging enable
      set security wpa-personal
      set passphrase "Fortinet1"
      set local-authentication enable
   end
```

Using bridged FortiAPs to increase scalability

The FortiGate wireless controller can support more FortiAP units in local bridge mode than in the normal mode. But this is only true if you configure some of your FortiAP units to operate in remote mode, which supports only local bridge mode SSIDs.

The Managed FortAP page (**WiFi Controller > Managed Devices > Managed FortiAP**) shows at the top right the current number of Managed FortiAPs and the maximum number that can be managed, "5/64" for example. The maximum number, however, is true only if all FortiAP units operate in remote mode. For more detailed information, consult the Maximum Values Table. For each FortiGate model, there are two maximum values for managed FortiAP units: the total number of FortiAPs and the number of FortiAPs that can operate in normal mode.

To configure FortiAP units for remote mode operation

1. Create at least one SSID with **Traffic Mode** set to **Local Bridge**.
2. Create a custom AP profile that includes only local bridge SSIDs.
3. Configure each managed FortiAP unit to use the custom AP profile. You also need to set the FortiAP unit's `wtp-mode` to `remote`, which is possible only in the CLI. The following example uses the CLI both to set `wtp-mode` and select the custom AP profile:

   ```
   config wireless-controller wtp
      edit FAP22B3U11005354
   ```

```
    set wtp-mode remote
    set wtp-profile 220B_bridge
end
```

Using Remote WLAN FortiAPs

Remote WLAN FortiAP models enable you to provide a pre-configured WiFi access point to a remote or traveling employee. Once plugged in at home or in a hotel room, the FortiAP automatically discovers the enterprise FortiGate WiFi controller over the Internet and broadcasts the same wireless SSID used in the corporate office. Communication between the WiFi controller and the FortiAP is secure, eliminating the need for a VPN.

Split tunneling

By default, all traffic from the remote FortiAP is sent to the FortiGate WiFi controller. If split tunneling is configured, only traffic destined for the corporate office networks is routed to the FortiGate unit. Other general Internet traffic is routed unencrypted through the local gateway. Split tunneling avoids loading the FortiGate unit with unnecessary traffic and allows access to local private networks at the FortiAP's location.

Note: Split tunneling in WiFi networks differs in implementation from split tunneling in VPN configurations.

By default, split tunneling options are not visible in the FortiGate GUI. You can make these options visible using the following CLI command:

```
config system global
   set gui-fortiap-split-tunneling enable
end
```

Split tunneling is configured in the FortiAP Profile and enabled in the SSID.

Configuring the FortiGate for remote FortiAPs

This section assumes that you have already defined SSIDs and now want to make them available to remote FortiAPs.

- Create FortiAP profiles for the Remote LAN FortiAP models
- If split tunneling will be used
  - enable Split Tunneling in the SSID
  - configure the split tunnel networks in the FortiAP profile

Creating FortiAP profiles

If you were not already using Remote LAN FortiAP models, you will need to create FortiAP profiles for them. In the FortiAP profile, you specify the SSIDs that the FortiAP will broadcast. For more information, see "Creating a FortiAP Profile" on page 817.

Configuring split tunneling - FortiGate GUI

Go to **WiFi Controller > WiFi Network > SSID** and edit your SSID. In the **WiFi Settings** section, enable **Split Tunneling**.

Go to **WiFi Controller > WiFi Network > FortiAP Profiles** and edit the FortiAP Profile(s) that apply to the AP types used in the WiFi network. In **Split Tunneling Subnets**, enter a comma-separated list all of the destination

IP address ranges that should ***not*** be routed through the the FortiGate WiFi controller. Packets for these destinations will instead be routed through the remote gateway local to the FortiAP.

The list of split tunneling subnets includes public Internet destinations and private subnets local to the FortiAP. Split tunneling public Internet destinations reduces traffic through the FortiGate unit. Split tunneling local private subnets allows these networks to be accessible to the client behind the FortiAP. Otherwise, private network IP destinations are assumed to be behind the FortiGate WiFi controller.

Configuring split tunneling - FortiGate CLI

In this example, split tunneling is configured on the example-ssid WiFi network. On FortiAP model 21D, traffic destined for the 192.168.x.x range will not be routed through the FortiGate WiFi controller. This private IP address range is typically used as a LAN by home routers.

```
config wireless-controller vap
   edit example-ssid
      set split-tunneling enable
   end

config wireless-controller wtp-profile
   edit FAP21D-default
      set split-tunneling-acl-local-ap-subnet enable
      config split-tunneling-acl
         edit 1
            set dest-ip 192.168.0.0 255.255.0.0
         end
      end
```

To enter multiple subnets, create a split-tunneling-acl entry for each one.

Configuring the FortiAP units

Prior to providing a Remote WLAN FortiAP unit to an employee, you need to preconfigure the AP to connect to your FortiGate WiFi controller.

To pre-configure a FortiAP

1. Connect the FortiAP to the FortiGate unit.
2. Go to **WiFi Controller > Managed Devices > Managed FortiAPs** and wait for the FortiAP to be listed. Click **Refresh** periodically to see the latest information. Note the **Connected Via** IP address.
3. Go to **System > Dashboard > Status**. In the CLI Console, log into the FortiAP CLI.
   For example, if the IP address is 192.168.1.4, enter:
   ```
   exec telnet 192.168.1.4
   ```
   Enter *admin* at the login prompt. By default, no password is set.
4. Enter the following commands to set the FortiGate WiFi controller IP address. This should be the FortiGate Internet-facing IP address, in this example 172.20.120.142.
   ```
   cfg -a AC_IPADDR_1=172.20.120.142
   cfg -c
   ```
5. Enter *exit* to log out of the FortiAP CLI.

Preauthorizing FortiAP units

By preauthorizing FortiAP units, you facilitate their automatic authorization on the network. Also, you can assign each unit a unique name, such as the employee's name, for easier tracking.

1. Go to **WiFi Controller > Managed Devices > Managed FortiAPs** and create a new entry.
2. Enter the **Serial Number** of the FortiAP unit and give it a **Name**. Select the appropriate **FortiAP Profile**.
3. Click **OK**.

Repeat this process for each FortiAP.

Features for high-density deployments

High-density environments such as auditoriums, classrooms, and meeting rooms present a challenge to WiFi providers. When a large number of mobile devices try to connect to a WiFi network, difficulties arise because of the limited number of radio channels and interference between devices.

FortiOS and FortiAP devices provide several tools to mitigate the difficulties of high-density environments.

Broadcast packet suppression

Broadcast packets are sent at a low data rate in WiFi networks, consuming valuable air time. Some broadcast packets are unnecessary or even potentially detrimental to the network and should be suppressed.

ARP requests and replies could allow clients to discover each other's IP addresses. On most WiFi networks, intra-client communication is not allowed, so these ARP requests are of no use, but they occupy air time.

DHCP (upstream) should be allowed so that clients can request an IP address using DHCP.

DHCP (downstream) should be suppressed because it would allow a client to provide DHCP service to other clients. Only the AP should do this.

NetBIOS is a Microsoft Windows protocol for intra-application communication. Usually this is not required in high-density deployments.

IPv6 broadcast packets can be suppressed if your network uses IPv4 addressing.

You can configure broadcast packet suppression in the CLI. For example, to suppress ARP, downstream DHCP, NetBIOS, and IPv6 packets on the conf-net network, enter:

```
config wireless-controller vap
   edit conf_net
      set broadcast-suppress arp-known arp-unknown arp-reply dhcp-down netbios-ns netbios-
          ds ipv6
   end
```

Multicast to unicast conversion

Multicast data such as streaming audio or video are sent at a low data rate in WiFi networks. This causes them to occupy considerable air time. FortiOS provides a multicast enhancement option that converts multicast streams to unicast. A unicast stream is sent to each client at high data rate that makes more efficient use of air time. You can configure multicast-to-unicast conversion in the CLI:

```
config wireless-controller vap
   edit <vap_name>
      set multicast-enhance enable
   end
```

Ignore weak or distant clients

Clients beyond the intended coverage area can have some impact on your high-density network. Your APs will respond to these clients' probe signals, consuming valuable air time. You can configure your WiFi network to ignore weak signals that most likely come from beyond the intended coverage area. The settings are available in the CLI:

```
config wireless-controller vap
   edit <vap_name>
      set probe-resp-suppression enable
      set probe-resp-threshold <level_int>
   end
```

vap_name is the SSID name.

probe-resp-threshold is the signal strength in dBm below which the client is ignored. The range is -95 to -20dBm. The default level is -80dBm.

Turn off 802.11b protocol

By disabling support for the obsolete 802.11b protocol, you can reduce the air time that beacons and management frames occupy. These signals will now be sent at a minimum of 6Mbps, instead of 1Mbps. You can set this for each radio in the FortiAP profile, using the CLI:

```
config wireless-controller wtp-profile
   edit <name_string>
      config radio-1
         set powersave-optimize no-11b-rate
      end
```

Limit power

High-density deployments usually cover a small area that has many clients. Maximum AP signal power is usually not required. Reducing the power reduces interference between APs. Fortinet recommends that you use FortiAP automatic power control. You can set this in the FortiAP profile.

1. Go to **WiFi Controller > WiFi Network > FortiAP Profiles** and edit the profile for your AP model.
2. For each radio, enable **Auto TX Power Control** and set the **TX Power Low** and **TX Power High** levels. The default range of 10 to 17dBm is recommended.

Use frequency band load-balancing

In a high-density environment is important to make the best use of the two WiFi bands, 2.4GHz and 5GHz. The 5GHz band has more non-overlapping channels and receives less interference from non-WiFi devices, but not all devices support it. Clients that are capable of 5GHz operation should be encouraged to use 5GHz rather than the 2.4GHz band.

To load-balance the WiFi bands, you enable Frequency Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi Controller > WiFi Network > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
   edit FAP221C-default
      config radio-1
         set frequency-handoff enable
      end
```

The FortiGate wireless controller continuously performs a scan of all clients in the area and records their signal strength (RSSI) on each band. When Frequency Handoff is enabled, the AP does not reply to clients on the 2.4GHz band that have sufficient signal strength on the 5GHz band. These clients can associate only on the 5GHz band. Devices that support only 2.4GHz receive replies and associate with the AP on the 2.4GHz band.

Setting the handoff RSSI threshold

The FortiAP applies load balancing to a client only if the client has a sufficient signal level on 5GHz. The minimum signal strength threshold is set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
   edit FAP221C-default
      set handoff-rssi 25
   end
```

`handoff-rssi` has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

AP load balancing

The performance of an AP is degraded if it attempts to serve too many clients. In high-density environments, multiple access points are deployed with some overlap in their coverage areas. The WiFi controller can manage the association of new clients with APs to prevent overloading.

To load-balance between APs, enable AP Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi Controller > WiFi Network > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
   edit FAP221C-default
      config radio-1
         set ap-handoff enable
      end
```

When an AP exceeds the threshold (the default is 30 clients), the overloaded AP does not reply to a new client that has a sufficient signal at another AP.

Setting the AP load balance threshold

The thresholds for AP handoff are set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
   edit FAP221C-default
      set handoff-sta-thresh 30
      set handoff-rssi 25
   end
```

`handoff-sta-thresh` sets the number of clients at which AP load balancing begins. It has a range of 5 to 35.

`handoff-rssi` Sets the minimum signal strength that a new client must have at an alternate AP for the overloaded AP to ignore the client. It has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

Application rate-limiting

To prevent particular application types from consuming too much bandwidth, you can use the FortiOS Application Control feature.

1. Go to **Security Profiles > Application Control**.
   You can use the default profile or create a new one.
2. Click the category, select **Traffic Shaping** and then select the priority for the category.
   Repeat for each category to be controlled.
3. Select **Apply**.
4. Go to **Policy & Objects > Policy > IPv4** and edit your WiFi security policy.
5. In **Security Profiles**, set **Application Control** ON and select the security profile that you edited.
6. Select **OK**.

Protecting the WiFi Network

Wireless IDS
WiFi data channel encryption

Wireless IDS

The FortiGate Wireless Intrusion Detection System (WIDS) monitors wireless traffic for a wide range of security threats by detecting and reporting on possible intrusion attempts. When an attack is detected the FortiGate unit records a log message.

You can create a WIDS profile to enable these types of intrusion detection:

- Asleap Attack—ASLEAP is a tool used to perform attacks against LEAP authentication.
- Association Frame Flooding—A Denial of Service attack using association requests. The default detection threshold is 30 requests in 10 seconds.
- Authentication Frame Flooding—A Denial of Service attack using association requests. The default detection threshold is 30 requests in 10 seconds.
- Broadcasting De-authentication—This is a type of Denial of Service attack. A flood of spoofed de-authentication frames forces wireless clients to de-athenticate, then re-authenticate with their AP.
- EAPOL Packet Flooding—Extensible Authentication Protocol over LAN (EAPOL) packets are used in WPA and WPA2 authentication. Flooding the AP with these packets can be a denial of service attack. Several types of EAPOL packets are detected: EAPOL-FAIL, EAPOL-LOGOFF, EAPOL-START, EAPOL-SUCC.
- Invalid MAC OUI—Some attackers use randomly-generated MAC addresses. The first three bytes of the MAC address are the Organizationally Unique Identifier (OUI), administered by IEEE. Invalid OUIs are logged.
- Long Duration Attack—To share radio bandwidth, WiFi devices reserve channels for brief periods of time. Excessively long reservation periods can be used as a denial of service attack. You can set a threshold between 1000 and 32 767 microseconds. The default is 8200.
- Null SSID Probe Response—When a wireless client sends out a probe request, the attacker sends a response with a null SSID. This causes many wireless cards and devices to stop responding.
- Spoofed De-authentication—Spoofed de-authentication frames form the basis for most denial of service attacks.
- Weak WEP IV Detection—A primary means of cracking WEP keys is by capturing 802.11 frames over an extended period of time and searching for patterns of WEP initialization vectors (IVs) that are known to be weak. WIDS detects known weak WEP IVs in on-air traffic.
- Wireless Bridge—WiFi frames with both the fromDS and ToDS fields set indicate a wireless bridge. This will also detect a wireless bridge that you intentionally configured in your network.

You can enable wireless IDS by selecting a WIDS Profile in your FortiAP profile.

To create a WIDS Profile

1. Go to **WiFi Controller > WiFi Network > WIDS Profile**.
2. Select a profile to edit or select **Create New**.
3. Select the types of intrusion to protect against.
   By default, all types are selected.
4. Select **Apply**.

You can also configure a WIDS profile in the CLI using the `config wireless-controller wids-profile` command.

Rogue AP detection

The WIDS profile includes settings for detection of unauthorized (rogue) access points in your wireless network. For more information, see Wireless network monitoring on page 870.

WiFi data channel encryption

Optionally, you can apply DTLS encryption to the data channel between the wireless controller and FortiAP units. This enhances security.

There are data channel encryption settings on both the FortiGate unit and the FortiAP units. At both ends, you can enable Clear Text, DTLS encryption, or both. The settings must agree or the FortiAP unit will not be able to join the WiFi network. By default, both Clear Text and DTLS-encrypted communication are enabled on the FortiAP unit, allowing the FortiGate setting to determine whether data channel encryption is used. If the FortiGate unit also enables both Clear Text and DTLS, Clear Text is used.

Data channel encryption settings are located in the Custom AP profile. If you use Automatic profile, only Clear Text is supported.

Data channel encryption is software-based and can affect performance. Verify that the system meets your performance requirements with encryption enabled.

Configuring encryption on the FortiGate unit

You can use the CLI to configure data channel encryption.

Enabling encryption

In the CLI, the `wireless wtp-profile` command contains a new field, `dtls-policy`, with options `clear-text` and `dtls-enabled`. To enable encryption in profile1 for example, enter:

```
config wireless-controller wtp-profile
   edit profile1
      set dtls-policy dtls-enabled
   end
```

Configuring encryption on the FortiAP unit

The FortiAP unit has its own settings for data channel encryption.

Enabling CAPWAP encryption - FortiAP web-based manager

1. On the **System Information** page, in **WTP Configuration > AC Data Channel Security**, select one of:
   - Clear Text
   - DTLS Enabled
   - Clear Text or DTLS Enabled (default)
2. Select **Apply**.

Enabling encryption - FortiAP CLI

You can set the data channel encryption using the AC_DATA_CHAN_SEC variable: 0 is Clear Text, 1 is DTLS Enabled, 2 (the default) is Clear Text or DTLS Enabled.

For example, to set security to DTLS and then save the setting, enter

```
cfg -a AC_DATA_CHAN_SEC=1
cfg -c
```

Wireless network monitoring

You can monitor both your wireless clients and other wireless networks that are available in your coverage area.

Monitoring wireless clients
Monitoring rogue APs
Suppressing rogue APs
Monitoring wireless network health

Monitoring wireless clients

To view connected clients on a FortiWiFi unit

1. Go to **WiFi Controller > Monitor > Client Monitor.**
   The following information is displayed:

SSID	The SSID that the client connected to.
FortiAP	The serial number of the FortiAP unit to which the client connected.
User	User name
IP	The IP address assigned to the wireless client.
Device	
Auth	The type of authentication used.
Channel	WiFi radio channel in use.
Bandwidth Tx/Rx	Client received and transmitted bandwidth, in Kbps.
Signal Strength / Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
Signal Strength	
Association Time	How long the client has been connected to this access point.

Results can be filtered. Select the filter icon on the column you want to filter. Enter the values to include or select NOT if you want to exclude the specified values.

Monitoring rogue APs

The access point radio equipment can scan for other available access points, either as a dedicated monitor or in idle periods during AP operation.

Discovered access points are listed in the **Rogue AP Monitor** list. You can then mark them as either Accepted or Rogue access points. This designation helps you to track access points. It does not affect anyone's ability to use these access points.

It is also possible to suppress rogue APs. See Monitoring rogue APs on page 870.

On-wire rogue AP detection technique

Other APs that are available in the same area as your own APs are not necessarily rogues. A neighboring AP that has no connection to your network might cause interference, but it is not a security threat. A rogue AP is an unauthorized AP connected to your wired network. This can enable unauthorized access. When rogue AP detection is enabled, the **On-wire** column in the **Rogue AP Monitor** list shows a green up-arrow on detected rogues.

Rogue AP monitoring of WiFi client traffic builds a table of WiFi clients and the Access Points that they are communicating through. The FortiGate unit also builds a table of MAC addresses that it sees on the LAN. The FortiGate unit's on-wire correlation engine constantly compares the MAC addresses seen on the LAN to the MAC addresses seen on the WiFi network.

There are two methods of Rogue AP on-wire detection operating simultaneously: Exact MAC address match and MAC adjacency.

Exact MAC address match

If the same MAC address is seen on the LAN and on the WiFi network, this means that the wireless client is connected to the LAN. If the AP that the client is using is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue. This scheme works for non-NAT rogue APs.

MAC adjacency

If an access point is also a router, it applies NAT to WiFi packets. This can make rogue detection more difficult. However, an AP's WiFi interface MAC address is usually in the same range as its wired MAC address. So, the MAC adjacency rogue detection method matches LAN and WiFi network MAC addresses that are within a defined numerical distance of each other. By default, the MAC adjacency value is 7. If the AP for these matching MAC addresses is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue.

Limitations

On-wire rogue detection has some limitations. There must be at least one WiFi client connected to the suspect AP and continuously sending traffic. If the suspect AP is a router, its WiFi MAC address must be very similar to its Ethernet port MAC address.

Logging

Information about detected rogue APs is logged and uploaded to your FortiAnalyzer unit, if you have one. By default, rogue APs generate an alert level log, unknown APs generate a warning level log. This log information can help you with PCI-DSS compliance requirements.

Rogue AP scanning as a background activity

Each WiFi radio can perform monitoring of radio channels in its operating band while acting as an AP. It does this by briefly switching from AP to monitoring mode. By default, a scan period starts every 300 seconds. Each second a different channel is monitored for 20ms until all channels have been checked.

During heavy AP traffic, it is possible for Spectrum Analysis background scanning to cause lost packets when the radio switches to monitoring. To reduce the probability of lost packets, you can set the CLI `ap-bgscan-idle`

field to delay the switch to monitoring until the AP has been idle for a specified period. This means that heavy AP traffic may slow background scanning.

The following CLI example configures default background rogue scanning operation except that it sets `ap-bgscan-idle` to require 100ms of AP inactivity before scanning the next channel.

```
config wireless-controller wtp-profile
   edit ourprofile
      config radio-1
         set wids-profile ourwidsprofile
         set spectrum-analysis enable
      end
   end
config wireless-controller wids-profile
   edit ourwidsprofile
      set ap-scan enable
      set rogue-scan enable
      set ap-bgscan-period 300
      set ap-bgscan-intv 1
      set ap-bgscan-duration 20
      set ap-bgscan-idle 100
   end
```

Configuring rogue scanning

All APs using the same FortiAP Profile share the same rogue scanning settings, unless override is configured.

To enable rogue AP scanning with on-wire detection - web-based manager

1. Go to **WiFi Controller > WiFi Network > WIDS Profiles**.
   On some models, the menu is **WiFi & Switch Controller**.
2. Select an existing WIDS Profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.
4. Select **Enable On-Wire Rogue AP Detection.**
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

To enable the rogue AP scanning feature in a custom AP profile - CLI

```
config wireless-controller wids-profile
   edit FAP220B-default
      set ap-scan enable
      set rogue-scan enable
   end
```

Exempting an AP from rogue scanning

By default, if Rogue AP Detection is enabled, it is enabled on all managed FortiAP units. Optionally, you can exempt an AP from scanning. You should be careful about doing this if your organization must perform scanning to meet PCI-DSS requirements.

To exempt an AP from rogue scanning - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAPs**.
2. Select which AP to edit.
3. In **Wireless Settings**, enable **Override Settings**.
4. Select **Do not participate in Rogue AP Scanning** and then select **OK**.

To exempt an AP from rogue scanning - CLI

This example shows how to exempt access point AP1 from rogue scanning.

```
config wireless-controller wtp
   edit AP1
      set override-profile enable
      set ap-scan disable
   end
```

MAC adjacency

You can adjust the maximum WiFi to Ethernet MAC difference used when determining whether an suspect AP is a rogue.

To adjust MAC adjacency

For example, to change the adjacency to 8, enter

```
config wireless-controller global
   set rogue-scan-mac-adjacency 8
end
```

Using the Rogue AP Monitor

Go to **WiFi Controller > Monitor > Rogue AP Monitor** to view the list of other wireless access points that are receivable at your location.

Information Columns Actual columns displayed depends on **Column Settings.**	
State	Rogue AP — Use this status for unauthorized APs that **On-wire** status indicates are attached to your wired networks. Accepted AP — Use this status for APs that are an authorized part of your network or are neighboring APs that are not a security threat. To see accepted APs in the list, select **Show Accepted**. Unclassified — This is the initial status of a discovered AP. You can change an AP back to unclassified if you have mistakenly marked it as Rogue or Accepted.
Online Status	Active AP Inactive AP Active ad-hoc WiFi device Inactive ad-hoc WiFi device
SSID	The wireless service set identifier (SSID) or network name for the wireless interface.
Security Type	The type of security currently being used.
Channel	The wireless radio channel that the access point uses.
MAC Address	The MAC address of the Wireless interface.
Vendor Info	The name of the vendor.
Signal Strength	The relative signal strength of the AP. Mouse over the symbol to view the signal-to-noise ratio.
Detected By	The name or serial number of the AP unit that detected the signal.
On-wire	A green up-arrow indicates a suspected rogue, based on the on-wire detection technique. A red down-arrow indicates AP is not a suspected rogue.
First Seen	How long ago this AP was first detected.
Last Seen	How long ago this AP was last detected.
Rate	Data rate in bps.

To change the Online Status of an AP, right-click it and select Mark Accepted or Mark Rogue.

Suppressing rogue APs

In addition to monitoring rogue APs, you can actively prevent your users from connecting to them. When suppression is activated against an AP, the FortiGate WiFi controller sends deauthentication messages to the rogue AP's clients, posing as the rogue AP, and also sends deauthentication messages to the rogue AP, posing as its clients. This is done using the monitoring radio.

Before enabling this feature, verify that operation of Rogue Suppression is compliant with the applicable laws and regulations of your region.

To enable rogue AP suppression, you must enable monitoring of rogue APs with the on-wire detection technique. See "Monitoring rogue APs". The monitoring radio must be in the Dedicated Monitor mode.

To activate AP suppression against a rogue AP

1. Go to **WiFi Controller > Monitor > Rogue AP Monitor.**
2. When you see an AP listed that is a rogue detected "on-wire", select it and then select **Mark > Mark Rogue**.
3. To suppress an AP that is marked as a rogue, select it and then select **Suppress AP**.

To deactivate AP suppression

1. Go to **WiFi Controller > Monitor > Rogue AP Monitor.**
2. Select the suppressed rogue AP and then select **Suppress AP > Unsuppress AP**.

Monitoring wireless network health

The Wireless Health Dashboard provides a comprehensive view of the health of your network's wireless infrastructure. The dashboard includes widgets to display

- AP Status - Active, Down or missing, up for over 24 hours, rebooted in past 24 hours
- Client Count Over Time - viewable for past hour, day, or 30 days
- Top Client Count Per-AP - separate widgets for 2.4GHz and 5GHz bands
- Top Wireless Interference - separate widgets for 2.4GHz and 5GHz bands, requires spectrum analysis to be enabled on the radios
- Login Failures Information

To view the Wireless Health dashboard, go to **WiFi Controller > Monitor > Wireless Health**.

Configuring wireless network clients

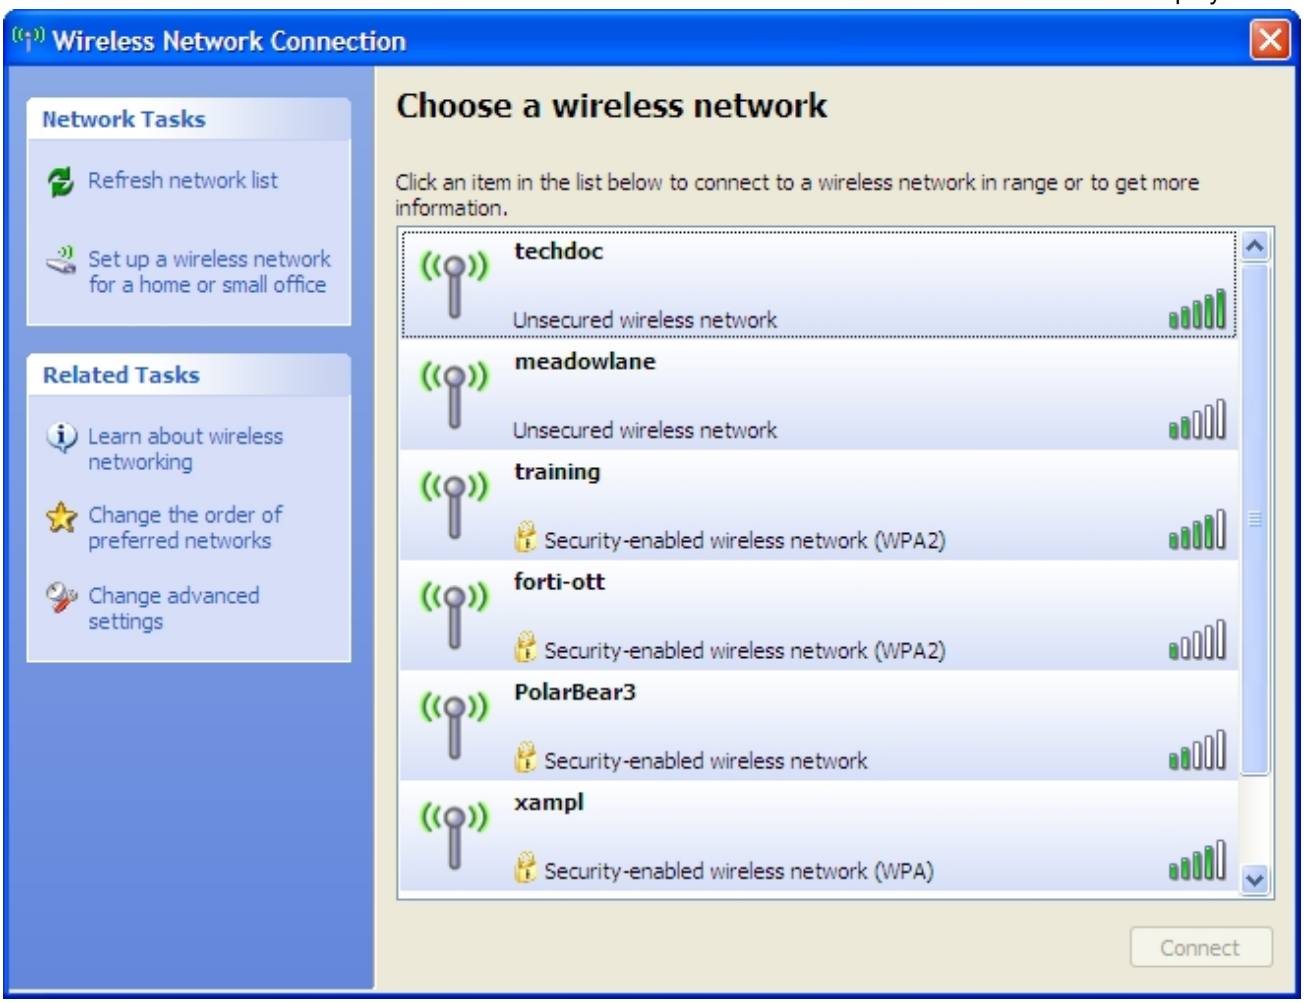
This chapter shows how to configure typical wireless network clients to connect to a wireless network with WPA-Enterprise security.

Windows XP client
Windows 7 client
Mac OS client
Linux client
Troubleshooting

Windows XP client

To configure the WPA-Enterprise network connection

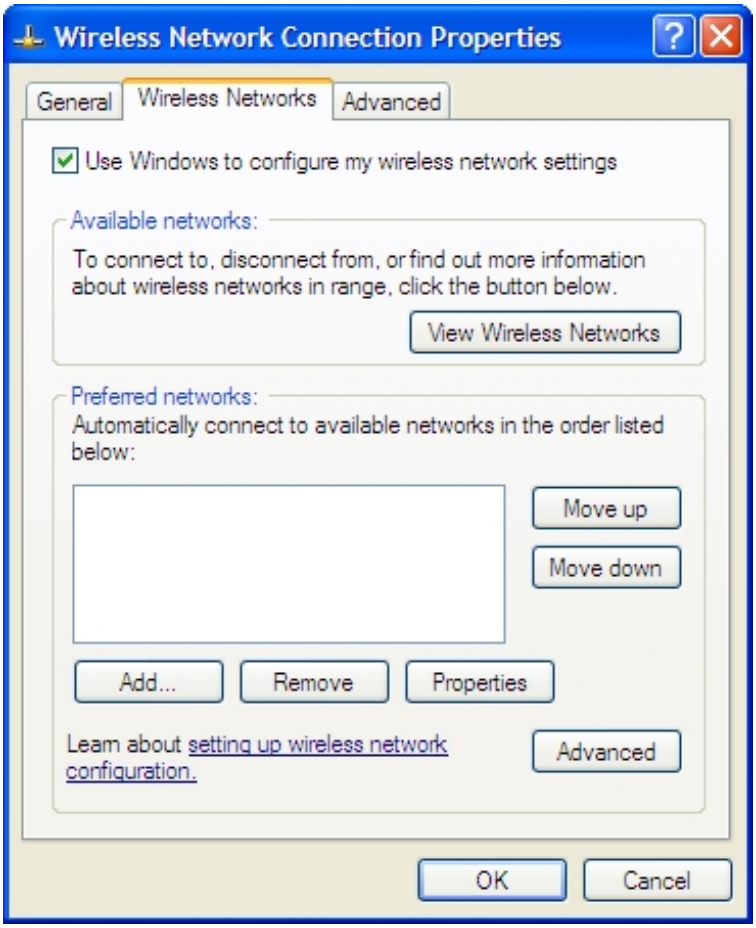
1. In the Windows Start menu, go to **Control Panel > Network Connections > Wireless Network Connection** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.



If you are already connected to another wireless network, the Connection Status window displays. Select **View Wireless Networks** on the **General** tab to view the list.

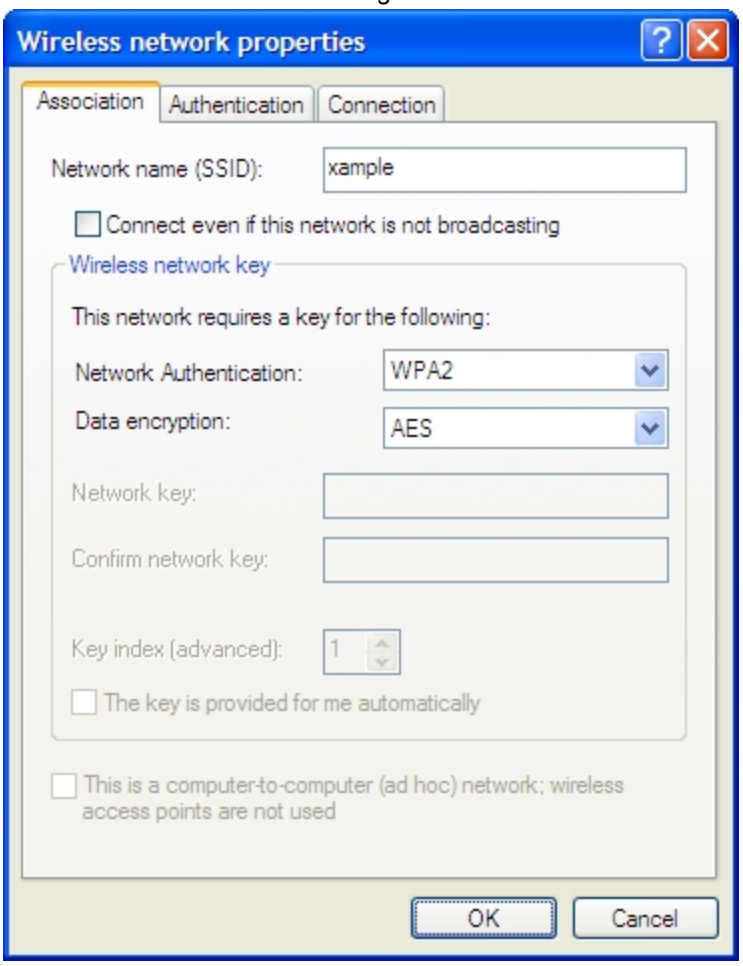
If the network broadcasts its SSID, it is listed. But do not try to connect until you have completed the configuration step below. Because the network doesn't use the Windows XP default security configuration, configure the client's network settings manually before trying to connect.

2. You can configure the WPA-Enterprise network to be accessible from the **View Wireless Networks** window even if it does not broadcast its SSID.
3. Select **Change Advanced Settings** and then select the **Wireless Networks** tab.



Any existing networks that you have already configured are listed in the **Preferred Networks** list.

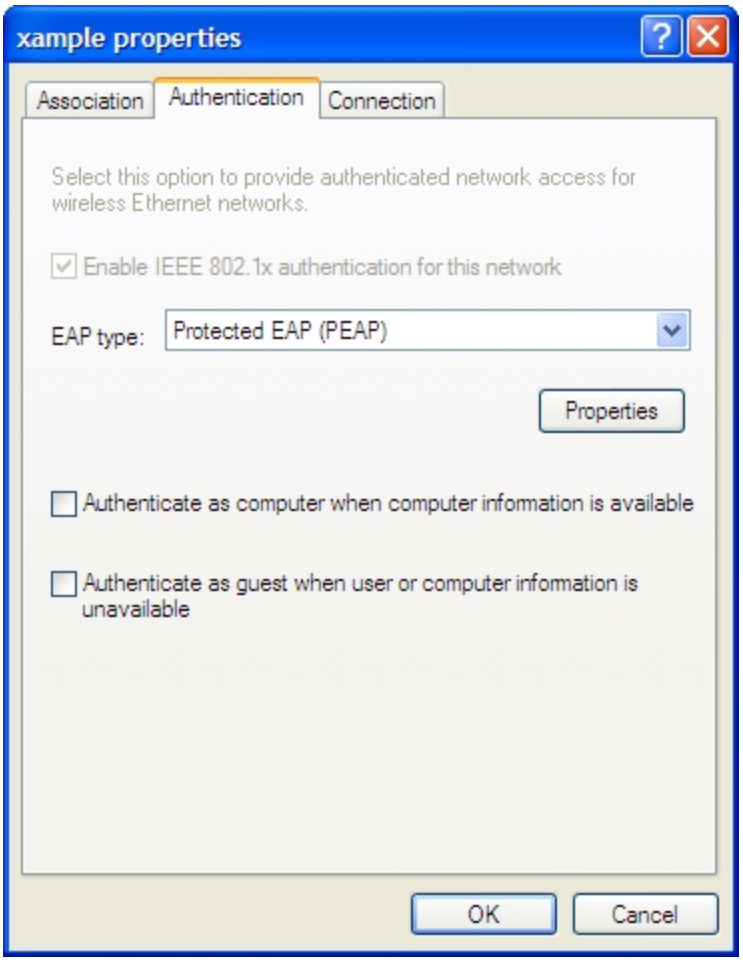
4. Select **Add** and enter the following information:



Network Name (SSID)	The SSID for your wireless network
Network Authentication	WPA2
Data Encryption	AES

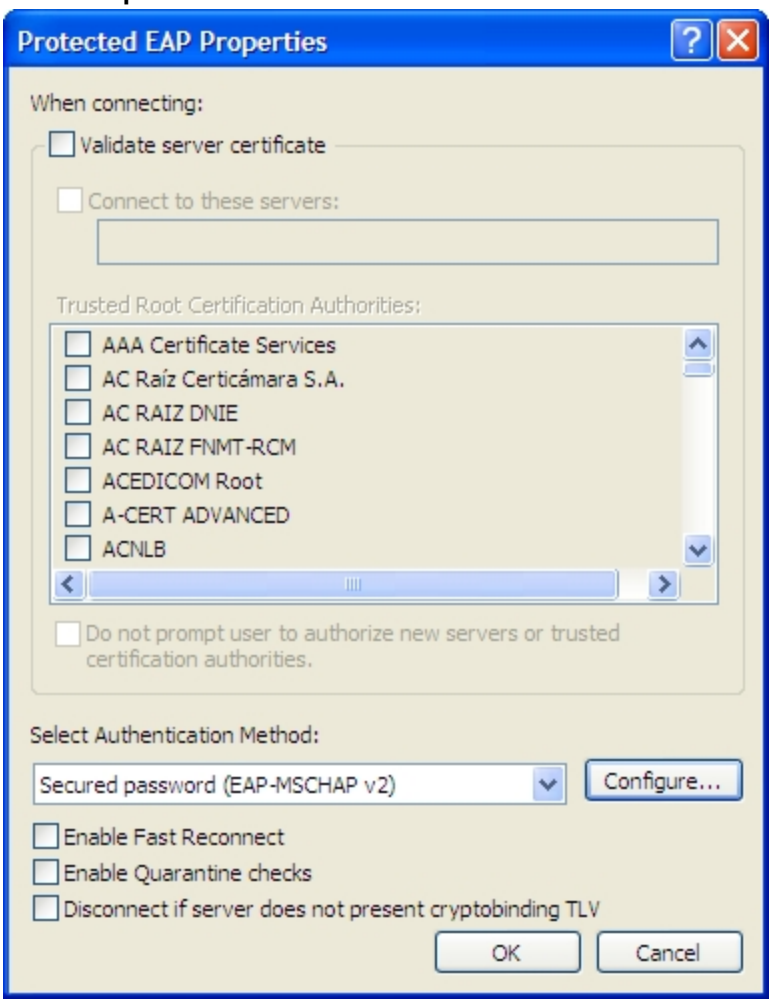
5. If this wireless network does not broadcast its SSID, select **Connect even if this network is not broadcasting** so that the network will appear in the **View Wireless Networks** list.

6. Select the **Authentication** tab.



7. In **EAP Type**, select **Protected EAP (PEAP)**.
8. Make sure that the other two authentication options are not selected.

9. Select **Properties**.



10. Make sure that **Validate server_certificate** is selected.
11. Select the server certificate UTN-USERFirst-Hardware.
12. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
13. Ensure that the remaining options are not selected.
14. Select **Configure**.

15. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
16. Select **OK**. Repeat until you have closed all of the **Wireless Network Connection Properties** windows.

To connect to the WPA-Enterprise wireless network

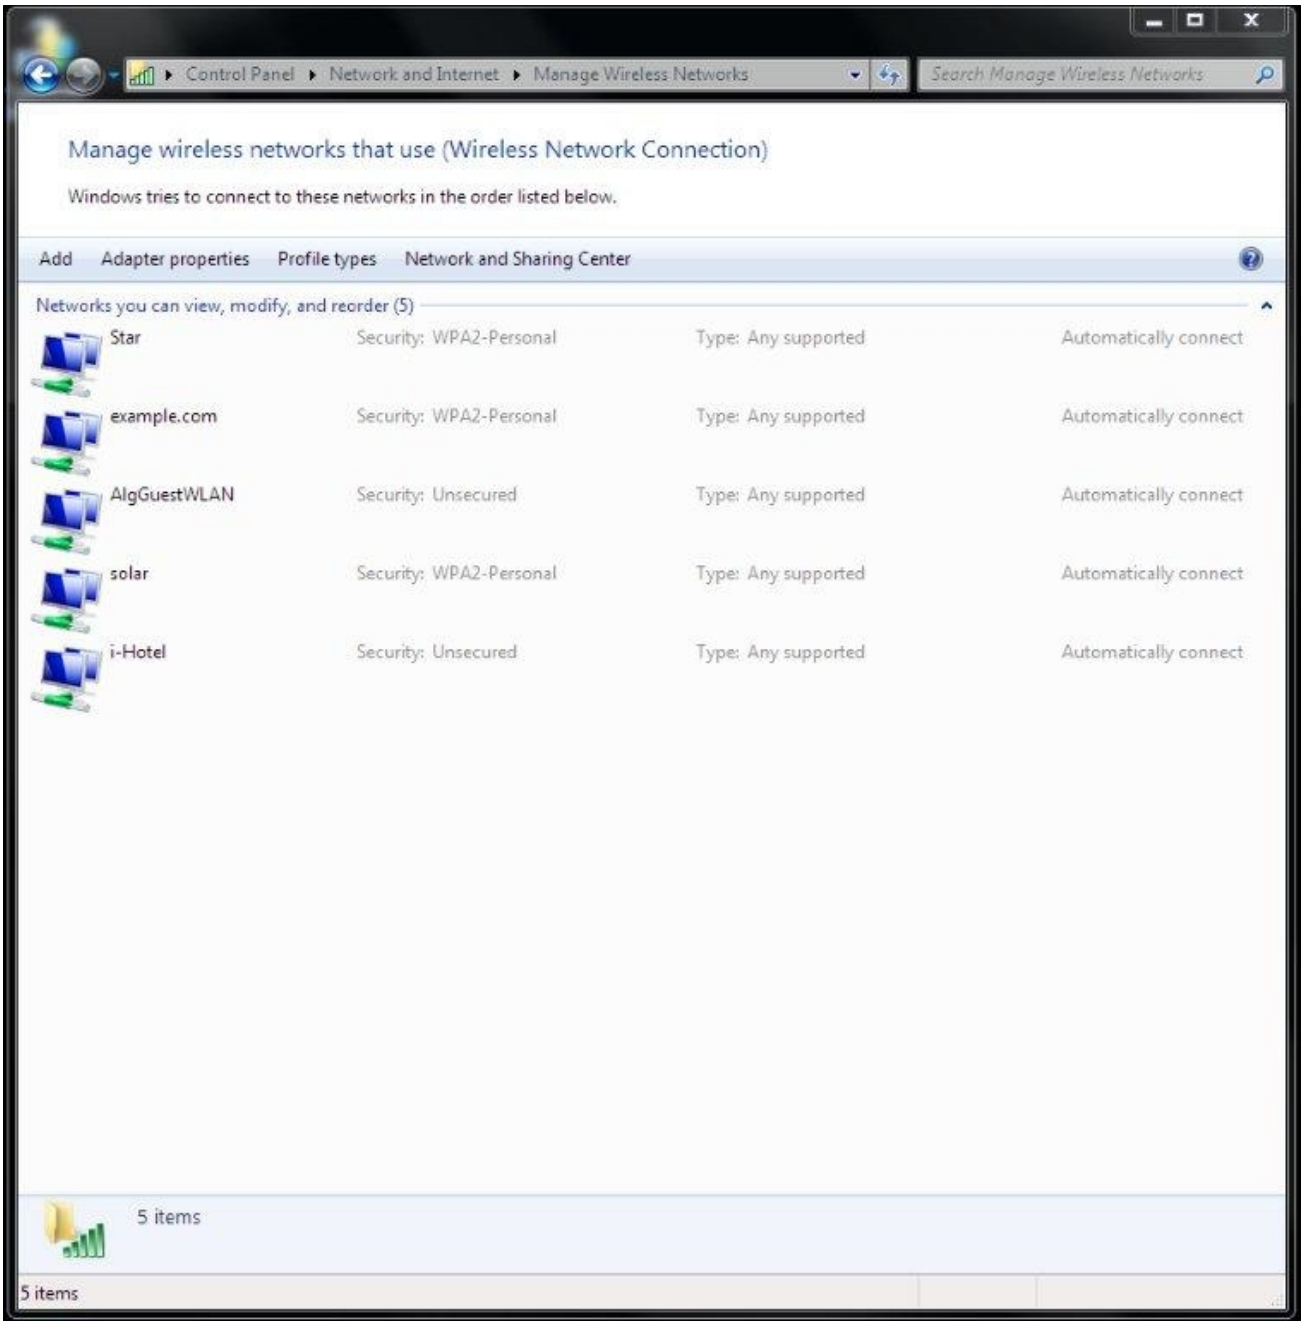
1. Select the wireless network icon in the Notification area of the Taskbar.
2. In the **View Wireless Networks** list, select the network you just added and then select **Connect**.
   You might need to log off of your current wireless network and refresh the list.
3. When the following popup displays, click on it.

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.

In future, Windows will automatically send your credentials when you log on to this network.

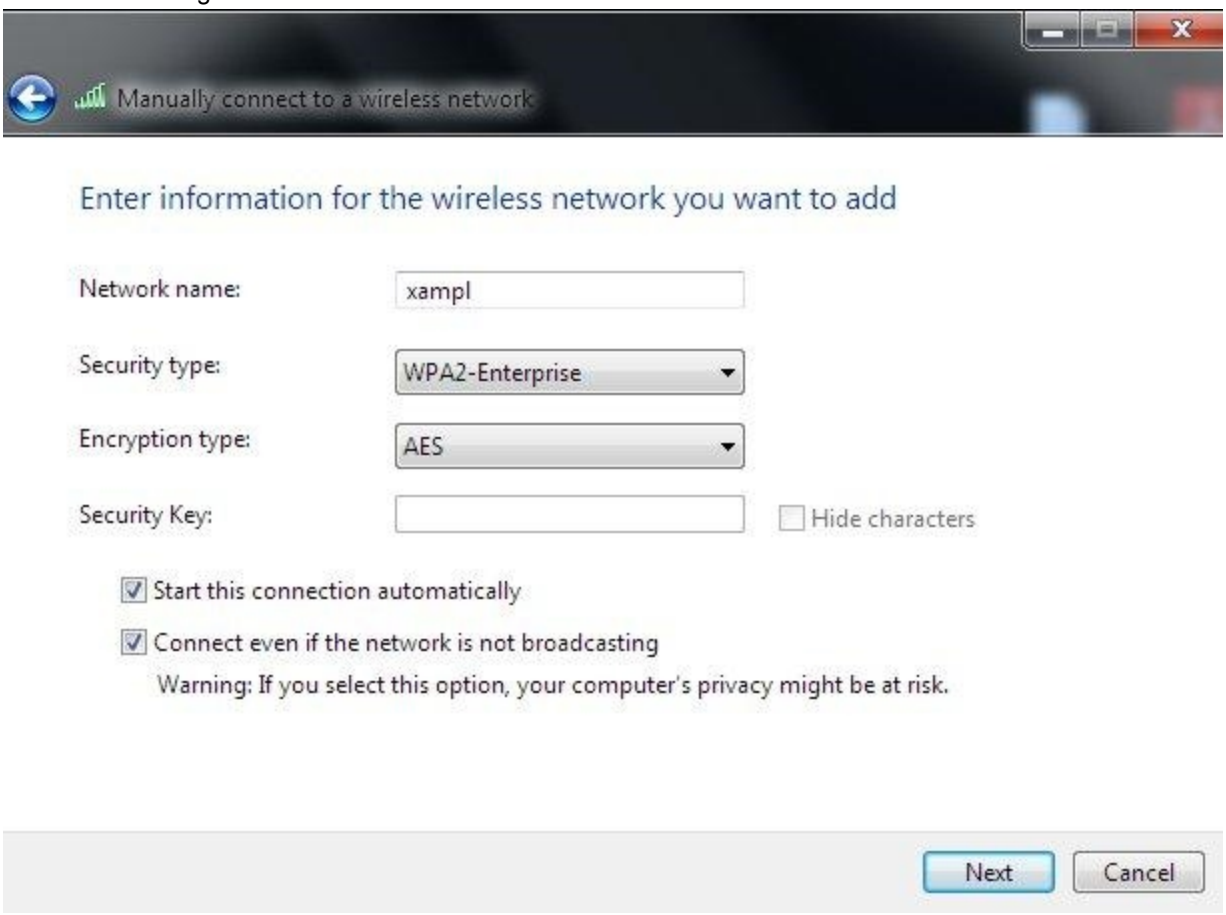
Windows 7 client

1. In the Windows Start menu, go to **Control Panel > Network and Internet > Network and Sharing Center > Manage Wireless Networks** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.



2. Do one of the following:
   - If the wireless network is listed (it broadcasts its SSID), select it from the list.
   - Select **Add** > **Manually create a network profile**.

3. Enter the following information and select **Next**.



Network name	Enter the SSID of the wireless network. (Required only if you selected **Add**.)
Security type	WPA2-Enterprise
Encryption type	AES
Start this connection automatically	Select
Connect even if the network is not broadcasting.	Select

The Wireless Network icon will display a popup requesting that you click to enter credentials for the network. Click on the popup notification.

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.
5. Select **Change connection settings**.
6. On the **Connection** tab, select **Connect automatically when this network is in range**.
7. On the **Security** tab, select the Microsoft PEAP authentication method and then select **Settings**.
8. Make sure that **Validate server_certificate** is selected.

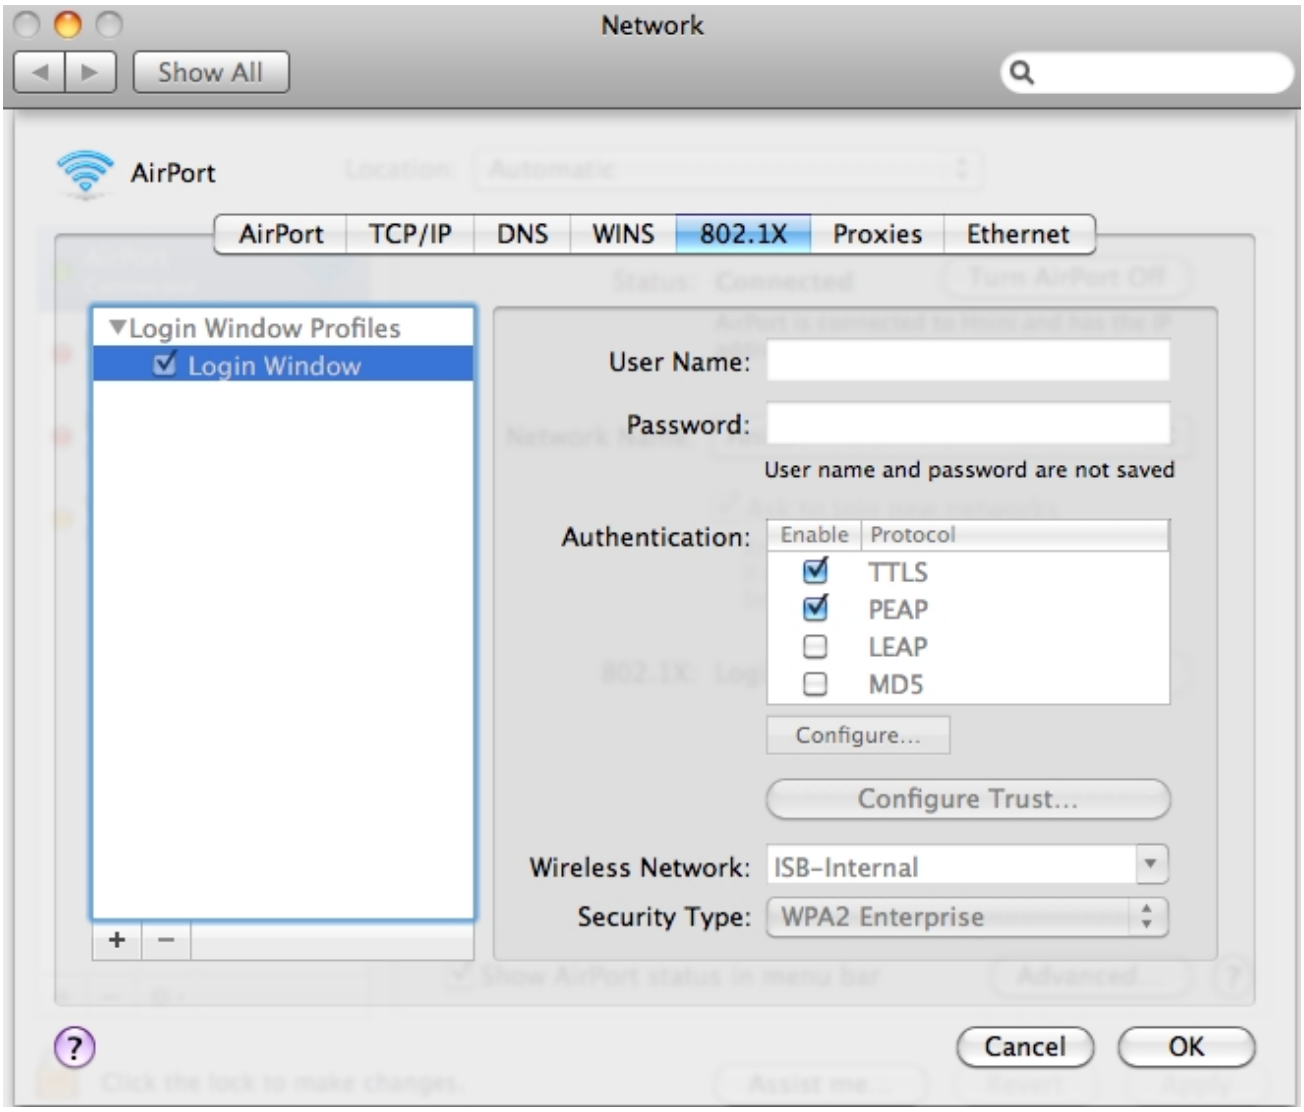
9. Select the server certificate UTN-USERFirst-Hardware.
10. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
11. Select **Configure**.

12. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
13. Ensure that the remaining options are not selected.
14. Select **OK**. Repeat until you have closed all of the **Wireless Network Properties** windows.

Mac OS client

To configure network preferences

1. Right-click the **AirPort** icon in the toolbar and select **Open Network Preferences**.
2. Select **Advanced** and then select the **802.1X** tab.



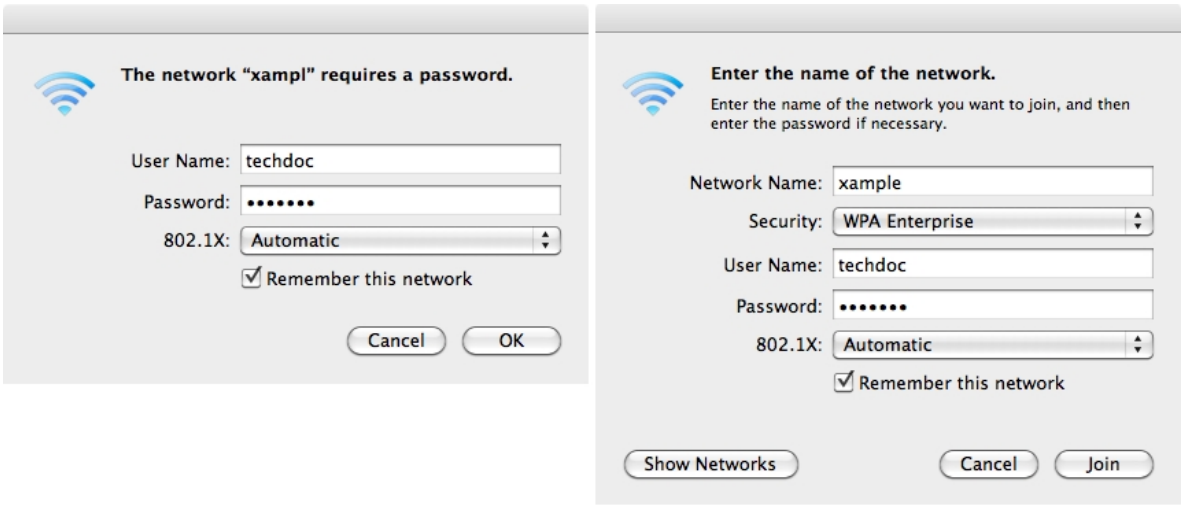
3. If there are no Login Window Profiles in the left column, select the + button and then select **Add Login Window Profile**.
4. Select the Login Window Profile and then make sure that both TTLS and PEAP are selected in **Authentication**.

To configure the WPA-Enterprise network connection

1. Select the **AirPort** icon in the toolbar.
2. Do one of the following:

- If the network is listed, select the network from the list.
- Select **Connect to Other Network**.

One of the following windows opens, depending on your selection.



3. Enter the following information and select **OK** or **Join**:

Network name	Enter the SSID of your wireless network. (Other network only)
Wireless Security	WPA Enterprise
802.1X	Automatic
Username **Password**	Enter your logon credentials for the wireless network.
Remember this network	Select.

You are connected to the wireless network.

Mac OS supports only PEAP with MSCHAPv2 authentication and therefore can authenticate only to a RADIUS server, not an LDAP or TACACS+ server

Linux client

This example is based on the Ubuntu 10.04 Linux wireless client.

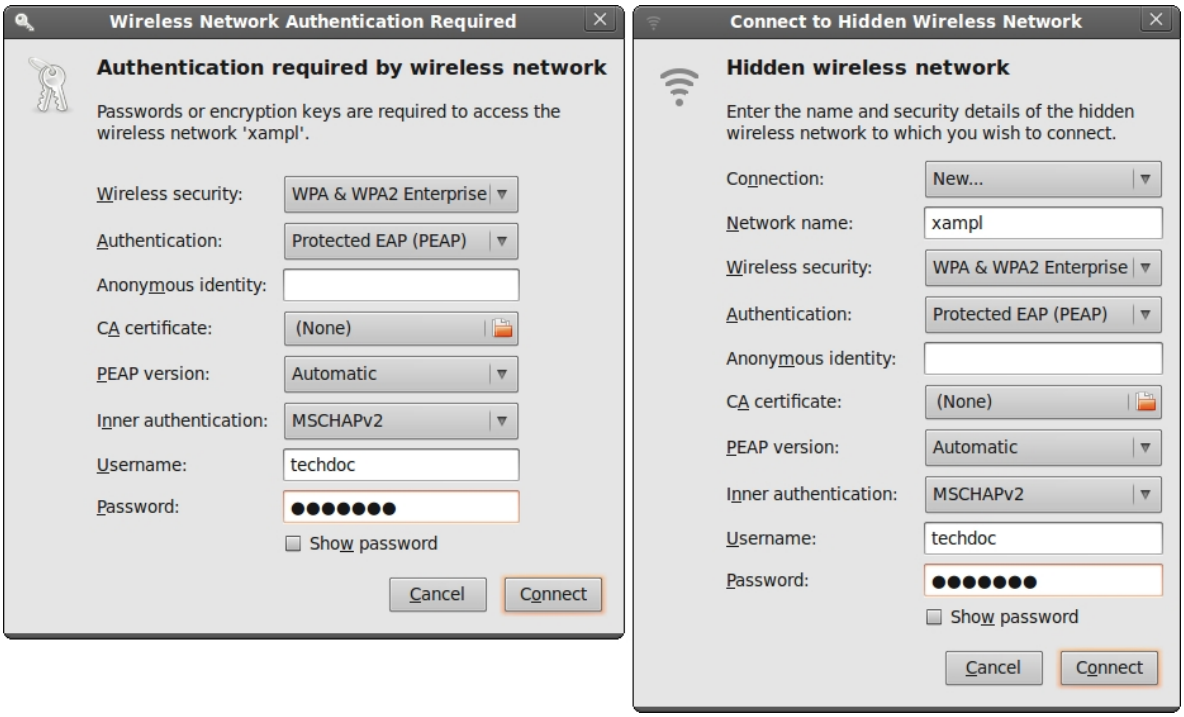
To connect to a WPA-Enterprise network

1. Select the Network Manager icon to view the Wireless Networks menu.

   Wireless networks that broadcast their SSID are listed in the **Available** section of the menu. If the list is long, it is continued in the **More Networks** submenu.

2. Do one of the following:
   - Select the network from the list (also check **More Networks**).
   - Select **Connect to Hidden Wireless Network**.

   One of the following windows opens, depending on your selection.



3. Enter the following information:

Connection	Leave as **New**. (Hidden network only)
Network name	Enter the SSID of your wireless network. (Hidden network only)
Wireless Security	WPA & WPA2 Enterprise
Authentication	Protected EAP (PEAP) for RADIUS-based authentication Tunneled TLS for TACACS+ or LDAP-based authentication
Anonymous identity	This is not required.
CA Certificate	If you want to validate the AP's certificate, select the UTN-USERFirst-Hardware root certificate. The default location for the certificate is /usr/share/ca-certificates/mozilla/.
PEAP version	Automatic (applies only to PEAP)
Inner authentication	MSCHAPv2 for RADIUS-based authentication PAP or CHAP for TACACS+ or LDAP-based authentication
Username **Password**	Enter your logon credentials for the wireless network.

4. If you did not select a CA Certificate above, you are asked to do so. Select Ignore.

5. Select **Connect.** You are connected to the wireless network.

To connect to a WPA-Enterprise network

1. Select the Network Manager icon to view the Wireless Networks menu.
2. Select the network from the list (also check **More Networks**).
   If your network is not listed (but was configured), select **Connect to Hidden Wireless Network**, select your network from the Connection drop-down list, and then select **Connect**.

Troubleshooting

Using tools provided in your operating system, you can find the source of common wireless networking problems.

Checking that client received IP address and DNS server information

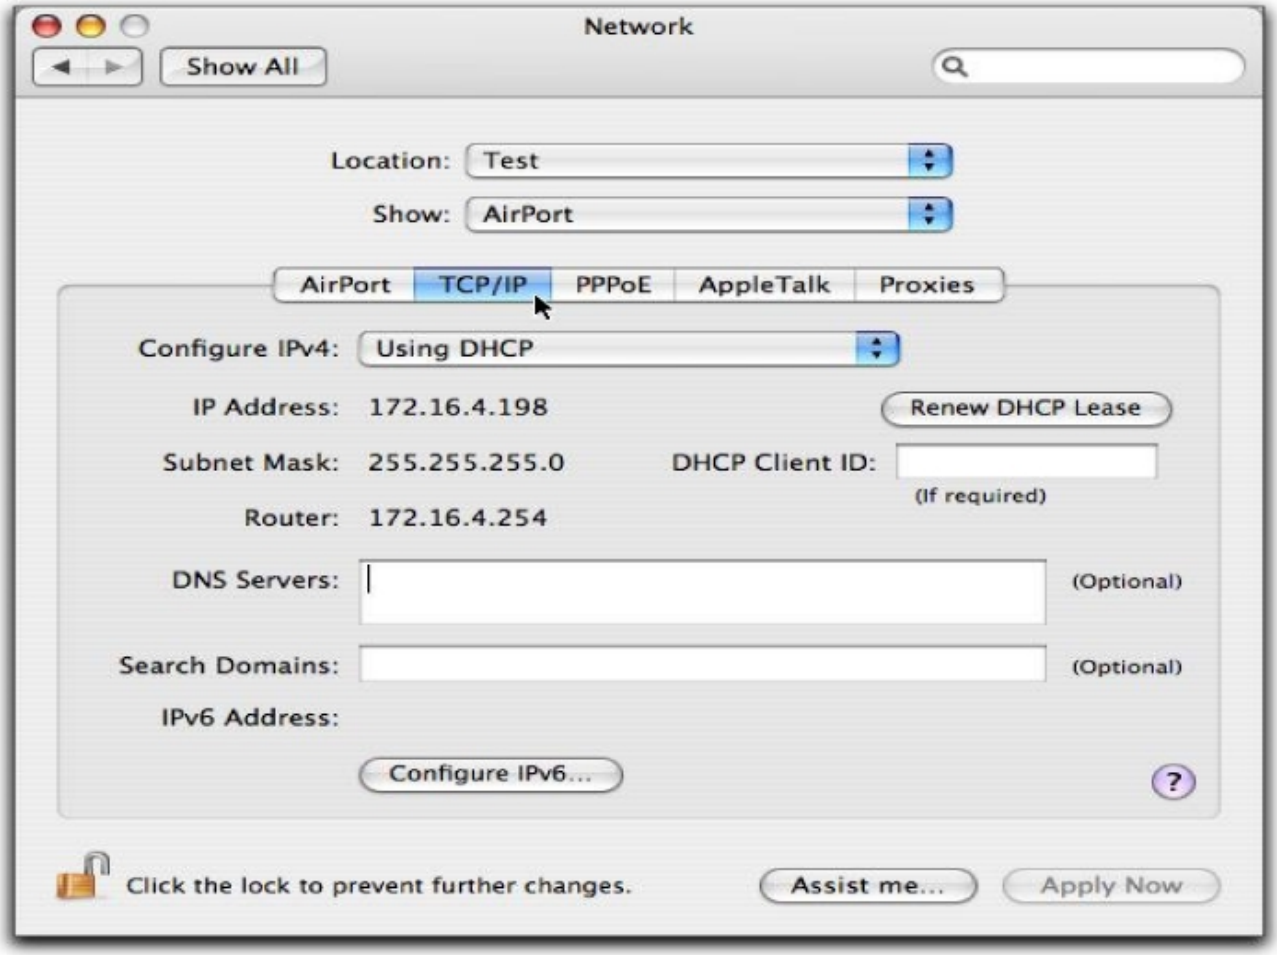
Windows XP

1. Double-click the network icon in the taskbar to display the **Wireless Network Connection Status** window.
   Check that the correct network is listed in the **Connection** section.
2. Select the **Support** tab.
   Check that the **Address Type** is **Assigned by DHCP**. Check that the **IP Address**, **Subnet Mask**, and **Default Gateway** values are valid.
3. Select **Details** to view the DNS server addresses.
   The listed address should be the DNS serves that were assigned to the WAP. Usually a wireless network that provides access to the private LAN is assigned the same DNS servers as the wired private LAN. A wireless network that provides guest or customer users access to the Internet is usually assigned public DNS servers.
4. If any of the addresses are missing, select **Repair**.
   If the repair procedure doesn't correct the problem, check your network settings.

Mac OS

1. From the Apple menu, open **System Preferences > Network**.
2. Select **AirPort** and then select **Configure**.

3. On the **Network** page, select the **TCP/IP** tab.



4. If there is no IP address or the IP address starts with 169, select **Renew DHCP Lease**.
5. To check DNS server addresses, open a terminal window and enter the following command:

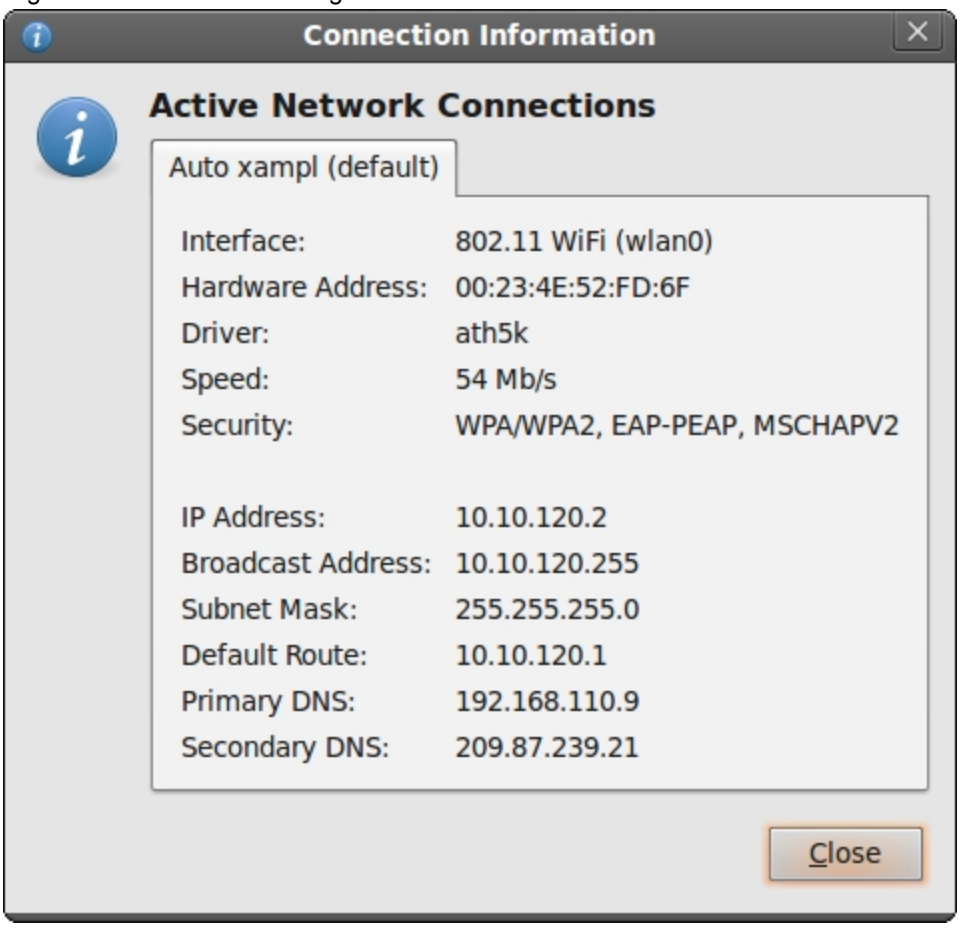
   ```
   cat /etc/resolv.conf
   ```

   Check the listed nameserver addresses. A network for employees should us the wired private LAN DNS server. A network for guests should specify a public DNS server.

Linux

This example is based on the Ubuntu 10.04 Linux wireless client.

1. Right-click the Network Manager icon and select **Connection Information**.



2. Check the IP address, and DNS settings. If they are incorrect, check your network settings.

Wireless network examples

This chapter provides an example wireless network configuration.

Basic wireless network
A more complex example

Basic wireless network

This example uses automatic configuration to set up a basic wireless network.

To configure this wireless network, you must:

- Configure authentication for wireless users
- Configure the SSID (WiFi network interface)
- Add the SSID to the FortiAP Profile
- Configure the firewall policy
- Configure and connect FortiAP units

Configuring authentication for wireless users

You need to configure user accounts and add the users to a user group. This example shows only one account, but multiple accounts can be added as user group members.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.
3. Enter a **User Name** and **Password** and then click **Next**.
4. Click **Next.**
5. Make sure that **Enable** is selected and then click **Create**.

To configure the WiFi user group - web-based manager

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	wlan_users
Type	**Firewall**
Members	Add users.

To configure a WiFi user and the WiFi user group - CLI

```
config user user
   edit "user01"
      set type password
      set passwd "asdf12ghjk"
```

```
    end
  config user group
    edit "wlan_users"
      set member "user01"
    end
```

Configuring the SSID

First, establish the SSID (network interface) for the network. This is independent of the number of physical access points that will be deployed. The network assigns IP addresses using DHCP.

To configure the SSID - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Enter the following information and select **OK**:

Interface Name		example_wifi_if
Traffic Mode		Tunnel to Wireless Controller
IP/Network Mask		10.10.110.1/24
Administrative Access		Ping (to assist with testing)
DHCP Server		Enable
	Address Range	10.10.110.2 - 10.10.110.199
	Netmask	255.255.255.0
	Default Gateway	Same As Interface IP
	DNS Server	Same as System DNS
SSID		example_wifi
Security Mode		WPA2 Enterprise
Authentication		Usergroup, select **wlan_users**.
Leave other settings at their default values.		

To configure the SSID - CLI

```
config wireless-controller vap
  edit example_wifi_if
    set ssid "example_wifi"
    set broadcast-ssid enable
    set security wpa-enterprise
    set auth usergroup
    set usergroup wlan_users
  end
config system interface
  edit example_wifi_if
    set ip 10.10.110.1 255.255.255.0
  end
```

```
config system dhcp server
   edit 0
        set default-gateway 10.10.110.1
      set dns-service default
      set interface "example_wifi_if"
      config ip-range
         edit 1
            set end-ip 10.10.110.199
            set start-ip 10.10.110.2
         end
      set netmask 255.255.255.0
   end
```

Adding the SSID to the FortiAP Profile

The radio portion of the FortiAP configuration is contained in the FortiAP Profile. By default, there is a profile for each platform (FortiAP model). You can create additional profiles if needed. The SSID needs to be specified in the profile.

To add the SSID to the FortiAP Profile - web-based manager

1. Go to **WiFi Controller > WiFi Network > FortiAP Profiles** and edit the profile for your model of FortiAP unit.
2. In **Radio 1** and **Radio 2**, add example_wifi in **SSID**.
3. Select **OK**.

Configuring firewall policies

A firewall policy is needed to enable WiFi users to access the Internet on port1. First you create firewall address for the WiFi network, then you create the example_wifi to port1 policy.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Name	wlan_user_net
Type	Subnet
Subnet / IP Range	10.10.110.0/24
Interface	example_wifi_if
Visibility	Enabled

To create a firewall address for WiFi users - CLI

```
config firewall address
   edit "wlan_user_net"
      set associated-interface "example_wifi_if"
      set subnet 10.10.110.0 255.255.255.0
   end
```

To create a firewall policy for WiFi users - web-based manager

1. Go to **Policy & Objects > Policy > IPv4**and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_wifi_if
Source Address	wlan_user_net
Outgoing Interface	port1
Destination Address	All
Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON. Select **Use Destination Interface Address** (default).
Leave other settings at their default values.	

To create a firewall policy for WiFi users - CLI

```
config firewall policy
   edit 0
      set srcintf "example_wifi"
      set dstintf "port1"
      set srcaddr "wlan_user_net"
      set dstaddr "all"
      set schedule always
      set service ALL
      set action accept
      set nat enable
   end
```

Connecting the FortiAP units

You need to connect each FortiAP unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **System > Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Dedicate to Extension Device** and set the **IP/Network Mask** to `192.168.8.1/255.255.255.0`.
3. Select **OK**.

This procedure automatically configures a DHCP server for the AP units. You can see this configuration in **System > Network > DHCP Server**.

To configure the interface for the AP unit - CLI

```
config system interface
   edit port3
      set mode static
      set ip 192.168.8.1 255.255.255.0
   end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
   edit 0
      set interface port3
      config exclude-range
         edit 1
            set end-ip 192.168.8.1
            set start-ip 192.168.8.1
         end
      config ip-range
         edit 1
            set end-ip 192.168.8.254
            set start-ip 192.168.8.2
         end
         set netmask 255.255.255.0
         set vci-match enable
         set vci-string "FortiAP"
   end
```

To connect a FortiAP unit - web-based manager

1. Go to **WiFi Controller > Managed Devices > Managed FortiAPs**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
   Recognition of the FortiAP unit can take up to two minutes.
   If FortiAP units are connected but cannot be recognized, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
   The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize.**
6. In **FortiAP Profile**, select the default profile for the FortiAP model.
   Override Settings should **not** be selected.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter
   ```
   config wireless-controller wtp
   ```

3. Wait 30 seconds, then enter `get`.
   Retry the `get` command every 15 seconds or so until the unit is listed, like this:
   ```
   == [ FAP22B3U10600118 ]
   wtp-id: FAP22B3U10600118
   ```

4. Edit the discovered FortiAP unit like this:
   ```
   edit FAP22B3U10600118
      set admin enable
   end
   ```

5. Repeat Steps 2 through 4 for each FortiAP unit.

A more complex example

This example creates multiple networks and uses custom AP profiles.

Scenario

In this example, Example Co. provides two wireless networks, one for its employees and the other for customers or other guests of its business. Guest users have access only to the Internet, not to the company's private network. The equipment for these WiFi networks consists of FortiAP-220B units controlled by a FortiGate unit.

The employee network operates in 802.11n mode on both the 2.4GHz and 5GHz bands. Client IP addresses are in the 10.10.120.0/24 subnet, with 10.10.120.1 the IP address of the WAP. The guest network also operates in 802.11n mode, but only on the 2.4GHz band. Client IP addresses are on the 10.10.115.0/24 subnet, with 10.10.115.1 the IP address of the WAP.

On FortiAP-220B units, the 802.11n mode also supports 802.11g and 802.11b clients on the 2.4GHz band and 802.11a clients on the 5GHz band.

The guest network WAP broadcasts its SSID, the employee network WAP does not.

The employees network uses WPA-Enterprise authentication through a FortiGate user group. The guest network features a captive portal. When a guest first tries to connect to the Internet, a login page requests logon credentials. Guests use numbered guest accounts authenticated by RADIUS. The captive portal for the guests includes a disclaimer page.

In this example, the FortiAP units connect to port 3 and are assigned addresses on the 192.168.8.0/24 subnet.

Configuration

To configure these wireless networks, you must:

- Configure authentication for wireless users
- Configure the SSIDs (network interfaces)
- Configure the AP profile
- Configure the WiFi LAN interface and a DHCP server
- Configure firewall policies

Configuring authentication for employee wireless users

Employees have user accounts on the FortiGate unit. This example shows creation of one user account, but you can create multiple accounts and add them as members to the user group.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.
3. Enter a **User Name** and **Password** and then click **Next**.
4. Click **Next**.
5. Make sure that **Enable** is selected and then click **Create**.

To configure the user group for employee access - web-based manager

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	employee-group
Type	**Firewall**
Members	Add users.

To configure a WiFi user and the user group for employee access - CLI

```
config user user
   edit "user01"
      set type password
      set passwd "asdf12ghjk"
   end
config user group
   edit "employee-group"
      set member "user01"
   end
```

The user authentication setup will be complete when you select the employee-group in the SSID configuration.

Configuring authentication for guest wireless users

Guests are assigned temporary user accounts created on a RADIUS server. The RADIUS server stores each user's group name in the Fortinet-Group-Name attribute. Wireless users are in the group named "wireless".

The FortiGate unit must be configured to access the RADIUS server.

To configure the FortiGate unit to access the guest RADIUS server - web-based manager

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information and select OK:

Name	guestRADIUS
Primary Server IP/Name	10.11.102.100
Primary Server Secret	grikfwpfdfg
Secondary Server IP/Name	Optional

Secondary Server Secret	Optional
Authentication Scheme	Use default, unless server requires otherwise.
Leave other settings at their default values.	

To configure the FortiGate unit to access the guest RADIUS server - CLI

```
config user radius
   edit guestRADIUS
      set auth-type auto
      set server 10.11.102.100
      set secret grikfwpfdfg
   end
```

To configure the user group for guest access - web-based manager

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	guest-group
Type	**Firewall**
Members	Leave empty.

3. Select **Add**.
4. Enter:

Remote Server	Select **guestRADIUS**.
Group Name	Select **Specify** and then enter `wireless`

5. Select **OK**.

To configure the user group for guest access - CLI

```
config user group
   edit "guest-group"
      set member "guestRADIUS"
      config match
         edit 0
            set server-name "guestRADIUS"
            set group-name "wireless"
         end
   end
```

The user authentication setup will be complete when you select the guest-group user group in the SSID configuration.

Configuring the SSIDs

First, establish the SSIDs (network interfaces) for the employee and guest networks. This is independent of the number of physical access points that will be deployed. Both networks assign IP addresses using DHCP.

To configure the employee SSID - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Enter the following information and select **OK**:

Interface Name	example_inc
IP/Netmask	10.10.120.1/24
Traffic Mode	Tunnel to Wireless Controller
Administrative Access	Ping (to assist with testing)
SSID	example_inc
Enable DHCP	Enable
Address Range	10.10.120.2 - 10.10.120.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
Security Mode	WPA/WPA2-Enterprise
Authentication	Select **Usergroup**, then select **employee-group.**
Leave other settings at their default values.	

To configure the employee SSID - CLI

```
config wireless-controller vap
   edit example_inc
      set ssid "example_inc"
      set security wpa-enterprise
      set auth usergroup
      set usergroup employee-group
   end
config system interface
   edit example_inc
      set ip 10.10.120.1 255.255.255.0
   end
config system dhcp server
   edit 0
      set default-gateway 10.10.120.1
      set dns-service default
      set interface example_inc
      config ip-range
         edit 1
```

```
            set end-ip 10.10.120.199
            set start-ip 10.10.120.2
         end
      set lease-time 7200
      set netmask 255.255.255.0
   end
```

To configure the example_guest SSID - web-based manager

1. Go to **WiFi Controller > WiFi Network > SSID** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_guest
IP/Netmask	10.10.115.1/24
Administrative Access	Ping (to assist with testing)
SSID	example_guest
Enable DHCP	Enable
Address Range	10.10.115.2 - 10.10.115.50
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Security Mode	Captive Portal
Customize Portal Messages	Select
User Groups	Select **guest-group**
Leave other settings at their default values.	

To configure the example_guest SSID - CLI

```
config wireless-controller vap
   edit example_guest
      set ssid "example_guest"
      set security captive-portal
      set selected-usergroups guest-group
   end
config system interface
   edit example_guest
      set ip 10.10.115.1 255.255.255.0
   end
config system dhcp server
   edit 0
      set default-gateway 10.10.115.1
      set dns-service default
      set interface "example_guest"
      config ip-range
         edit 1
```

```
            set end-ip 10.10.115.50
            set start-ip 10.10.115.2
        end
        set lease-time 7200
        set netmask 255.255.255.0
    end
```

Configuring the FortiAP profile

The FortiAP Profile defines the radio settings for the networks. The profile provides access to both Radio 1 (2.4GHz) and Radio 2 (5GHz) for the employee virtual AP, but provides access only to Radio 1 for the guest virtual AP.

To configure the FortiAP Profile - web-based manager

1. Go to **WiFi Controller > WiFi Network > FortiAP Profiles** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_AP
Platform	FAP220B
Radio 1	
Mode	Access Point
Spectrum Analysis	Enable
Radio Resource Provision	Not enabled
Band	802.11n
Short Guard Interval	Not enabled
Channel	Select 1, 6, and 11.
Tx Power	100%
SSID	Select **example_inc** and **example_guest**.
Radio 2	
Mode	Access Point
Spectrum Analysis	Enable
Radio Resource Provision	Enabled
Band	802.11n_5G
Short Guard Interval	Not enabled
20/40 MHz Channel Width	Not enabled
Channel	Select all.

Tx Power	100%
SSID	Select **example_inc**.

To configure the AP Profile - CLI

```
config wireless-controller wtp-profile
   edit "example_AP"
      config platform
         set type 220B
      end
      config radio-1
         set ap-bgscan enable
         set band 802.11n
         set channel "1" "6" "11"
         set vaps "example_inc" "example_guest"
      end
      config radio-2
         set ap-bgscan enable
         set band 802.11n-5G
         set channel "36" "40" "44" "48" "149" "153" "157" "161" "165"
         set vaps "example_inc"
      end
```

Configuring firewall policies

Identity-based firewall policies are needed to enable the WLAN users to access the Internet on Port1. First you create firewall addresses for employee and guest users, then you create the firewall policies.

To create firewall addresses for employee and guest WiFi users

1. Go to **Firewall Objects > Address > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Address Name	employee-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.120.0/24
Interface	example_inc

3. Select **Create New**, enter the following information and select **OK**.

Address Name	guest-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.115.0/24
Interface	example_guest

To create firewall policies for employee WiFi users - web-based manager

1. Go to **Policy > Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Source Interface/Zone	example_inc
Source Address	employee-wifi-net
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select **UTM** and set up UTM features for wireless users.
4. Select **OK**.
5. Repeat steps 1 through 4 but select Internal as the Destination Interface/Zone to provides access to the ExampleCo private network.

To create firewall policies for employee WiFi users - CLI

```
config firewall policy
   edit 0
      set srcintf "employee_inc"
      set dstintf "port1"
      set srcaddr "employee-wifi-net"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
      set nat enable
      set schedule "always"
      set service "ANY"
   next
   edit 0
      set srcintf "employee_inc"
      set dstintf "internal"
      set srcaddr "employee-wifi-net"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
      set nat enable
      set schedule "always"
      set service "ANY"
   end
```

To create a firewall policy for guest WiFi users - web-based manager

1. Go to **Policy > Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Source Interface/Zone	example_guest
Source Address	guest-wifi-net
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select **UTM** and set up UTM features for wireless users.
4. Select **OK**.

To create a firewall policy for guest WiFi users - CLI

```
config firewall policy
   edit 0
      set srcintf "example_guest"
      set dstintf "port1"
      set srcaddr "guest-wifi-net"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
      set nat enable
   end
```

Connecting the FortiAP units

You need to connect each FortiAP-220A unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **System > Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Manual** and set the **IP/Netmask** to `192.168.8.1`.
3. Enable **Connect FortiAP to this interface and** set **Reserve IP addresses for FortiAP** to `192.168.8.2 - 192.168.8.9`.

This step automatically configures a DHCP server for the AP units.

4. Select **OK**.

To configure the interface for the AP unit - CLI

```
config system interface
   edit port3
      set mode static
      set ip 192.168.8.1 255.255.255.0
   end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
   edit 0
      set interface port3
      config ip-range
         edit 1
            set end-ip 192.168.8.9
            set start-ip 192.168.8.2
         end
      set netmask 255.255.255.0
      set vci-match enable
      set vci-string "FortiAP"
   end
```

To connect a FortiAP-220A unit - web-based manager

1. Go to **WiFi Controller > Managed Access Points > Managed FortiAP**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
   Recognition of the FortiAP unit can take up to two minutes.
   If there is persistent difficulty recognizing FortiAP units, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
   The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize.**
6. In the **AP Profile,** select **[Change]** and then select the **example_AP** profile.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP-220A unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter:
   ```
   config wireless-controller wtp
   ```
3. Wait 30 seconds, then enter `get`.
   Retry the `get` command every 15 seconds or so until the unit is listed, like this:
   ```
   == [ FAP22A3U10600118 ]
   wtp-id: FAP22A3U10600118
   ```
4. Edit the discovered FortiAP unit like this:

```
edit FAP22A3U10600118
   set admin enable
   set wtp-profile example_AP
end
```

5. Repeat Steps 2 through 4 for each FortiAP unit.

Using a FortiWiFi unit as a client

A FortiWiFi unit by default operates as a wireless access point. But a FortiWiFi unit can also operate as a wireless client, connecting the FortiGate unit to another wireless network.

Use of client mode
Configuring client mode

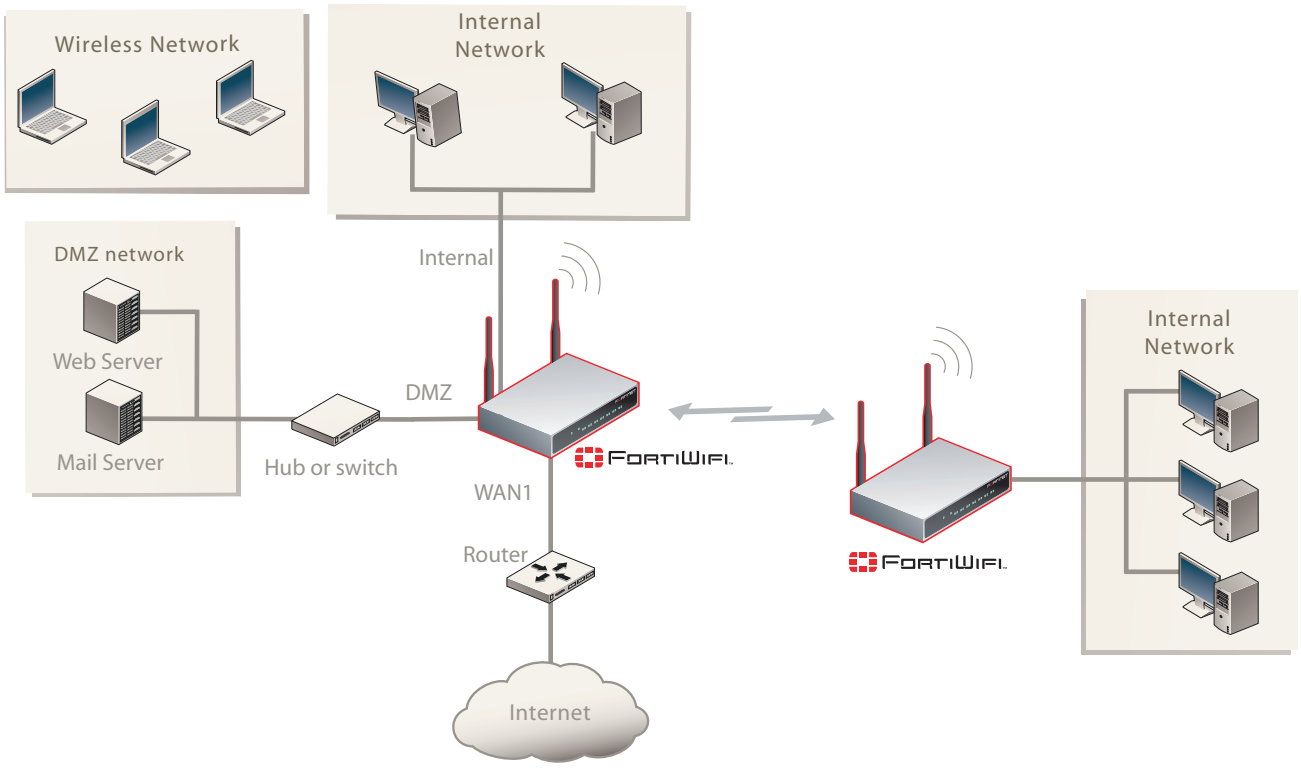
Use of client mode

In client mode, the FortiWiFi unit connects to a remote WiFi access point to access other networks or the Internet. This is most useful when the FortiWiFi unit is in a location that does not have a wired infrastructure.

For example, in a warehouse where shipping and receiving are on opposite sides of the building, running cables might not be an option due to the warehouse environment. The FortiWiFi unit can support wired users using its Ethernet ports and can connect to another access point wirelessly as a client. This connects the wired users to the network using the 802.11 WiFi standard as a backbone.

Note that in client mode the FortiWiFi unit cannot operate as an AP. WiFi clients cannot see or connect to the FortiWifi unit in Client mode.

Fortinet unit in Client mode



Configuring client mode

To set up the FortiAP unit as a WiFi client, you must use the CLI. Before you do this, be sure to remove any AP WiFi configurations such as SSIDs, DHCP servers, policies, and so on.

To configure wireless client mode

1. Change the WiFi mode to client.
   In the CLI, enter the following commands:
   ```
   config system global
      set wireless-mode client
   end
   ```
   Respond “y” when asked if you want to continue. The FortiWiFi unit will reboot.
2. Configure the WiFi interface settings.
   For example, to configure the client for WPA-Personal authentication on the **our_wifi** SSID with passphrase **justforus**, enter the following in the CLI:
   ```
   config system interface
      edit wifi
         set mode dhcp
         config wifi-networks
            edit 0
               set wifi-ssid our_wifi
               set wifi-security wpa-personal
               set wifi-passphrase "justforus"
            end
      end
   ```
   The WiFi interface client_wifi will receive an IP address using DHCP.
3. Configure a wifi to port1 policy.
   You can use either CLI or web-based manager to do this. The important settings are:

Incoming Interface (srcintf)	wifi
Source Address (srcaddr)	all
Outgoing Interface (dstintf)	port1
Destination Address (dstaddr)	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Selected

Support for location-based services

FortiOS supports location-based services by collecting information about WiFi devices near FortiGate-managed access points, even if the devices don't associate with the network.

Overview
Configuring location tracking
Viewing device location data on the FortiGate unit

Overview

WiFi devices broadcast packets as they search for available networks. The FortiGate WiFi controller can collect information about the interval, duration, and signal strength of these packets. The Euclid Analytics service uses this information to track the movements of the device owner. A typical application of this technology is to analyze shopper behavior in a shopping center. Which stores do people walk past? Which window displays do they stop to look at? Which stores do they enter and how long do they spend there? The shoppers are not personally identified, each is known only by the MAC address of their WiFi device.

After enabling location tracking on the FortiGate unit, you can confirm that the feature is working by using a specialized diagnostic command to view the raw tracking data. The Euclid Analytics service obtains the same data in its proprietary format using a JSON inquiry through the FortiGate unit's web-based manager interface.

Configuring location tracking

You can enable location tracking in any FortiAP profile, using the CLI. For each radio, set the `station-locate` field to `enable`. For example:

```
config wireless-controller wtp-profile
   edit "FAP220B-locate"
      set ap-country US
      config platform
         set type 220B
      end
      config radio-1
         set station-locate enable
      end
      config radio-2
         set station-locate enable
      end
   end
```

Viewing device location data on the FortiGate unit

You can use the FortiGate CLI to list located devices. This is mainly useful to confirm that the location data feature is working, You can also reset device location data.

To list located devices

```
diag wireless-controller wlac -c sta-locate
```

To reset device location data

```
diag wireless-controller wlac -c sta-locate-reset
```

Example output

The following output shows data for three WiFi devices.

```
FWF60C3G11004319 # diagnose wireless-controller wlac -c sta-locate
   sta_mac vfid rid base_mac freq_lst frm_cnt frm_fst frm_last intv_sum intv2_sum intv3_
       sum intv_min intv_max signal_sum signal2_sum signal3_sum sig_min sig_max sig_fst
       sig_last ap

   00:0b:6b:22:82:61 0
   FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 257 708 56 651 1836 6441 0 12 -21832
       1855438 -157758796 -88 -81 -84 -88 0

   00:db:df:24:1a:67 0
   FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 42 1666 41 1625 97210 5831613 0 60 -3608
       310072 -26658680 -90 -83 -85 -89 0

   10:68:3f:50:22:29 0
   FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 102 1623 58 1565 94136 5664566 0 60 -8025
       631703 -49751433 -84 -75 -78 -79 0
```

The output for each device appears on two lines. The first line contains only the device MAC address and the VLAN ID. The second line begins with the ID (serial number) of the FortiWiFi or FortiAP unit that detected the device, the AP's MAC address, and then the fields that the Euclid service uses. Because of its length, this line wraps around and displays as multiple lines.

Reference

This chapter provides some reference information pertaining to wireless networks.

FortiAP web-based manager
Wireless radio channels
FortiAP CLI

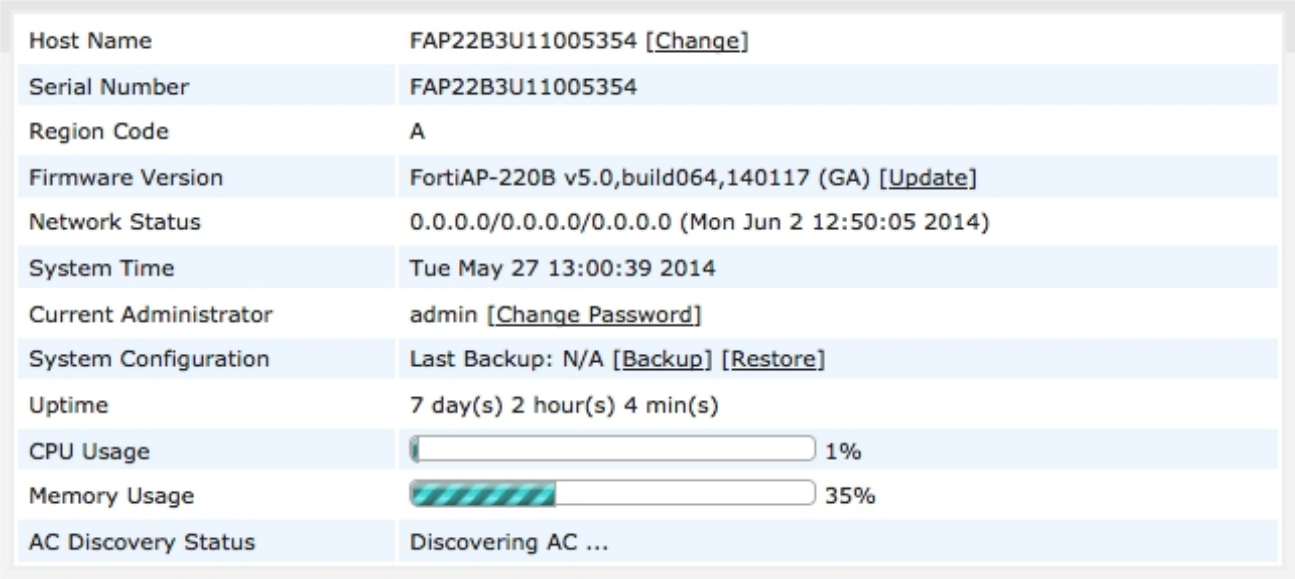
FortiAP web-based manager

You can access the FortiAP unit's built-in web-based manager. This is useful to adjust settings that are not available through the FortiGate unit's WiFi Controller. Logging into the FortiAP web-based manager is similar to logging into the FortiGate web-based manager.

System Information

Status

The **Status** section provides information about the FortiAP unit.



You can:

- Select **Change** to change the **Host Name**.
- Select **Update** in **Firmware Version** to upload a new FortiAP firmware file from your computer.
- Select **Change Password** to change the administrator password.
- Select **Backup** to save the current FortiAP configuration as a file on your computer.
- Select Restore to load a configuration into your FortiAP unit from a file on your computer.

Network Configuration

Select DHCP or select Static and specify the IP address, netmask, and gateway IP address. **Administrative Access** settings affect access after the FortiAP has been authorized. By default, **HTTP** access needed to access the FortiAP web-based manager is enabled, but **Telnet** access is not enabled.

Connectivity

These settings determine how the FortiAP unit connects to the FortiGate WiFi controller.

Uplink	Ethernet - wired connection to the FortiGate unit (default) Mesh - WiFi mesh connection Ethernet with mesh backup support
Mesh AP SSID	Enter the SSID of the mesh root. Default: fortinet.mesh.root
Mesh AP Password	Enter password for the mesh SSID.
Ethernet Bridge	Bridge the mesh SSID to the FortiAP Ethernet port. This is available only whe **Uplink** is **Mesh**.

WTP Configuration

AC Discovery Type settings affect how the FortiAP unit discovers a FortiGate WiFi controller. By default, this is set to Auto which causes the FortiAP unit to cycle through all of the discovery methods until successful. For more information see Controller discovery methods.

AC Discovery Type	Static, DHCP, DNS, Broadcast, Multicast, Auto
AC Control Port	Default port is 5246.
AC IP Address 1 **AC IP Address 2** **AC IP Address 3**	You enter up to three WiFi controller IP addresses for static discovery. Routing must be properly configured in both directions.
AC Host Name 1 **AC Host Name 2** **AC Host Name 3**	As an alternetive to AC IP addresses, you can enter their fully qualified domain names (FQDNs).
AC Discovery Multicast Address	224.0.1.140
AC Discovery DHCP Option Code	When using DHCP discovery, you can configure the DHCP server to provide the controller address. By default the FortiAP unit expects this in option 138.

AC Data Channel Security by default accepts either DTLS-encrypted or clear text data communication with the WiFi controller. You can change this setting to require encryption or to use clear text only.

Wireless Information

The Wireless Information page provides current information about the operation of the radios and the type Uplink in use.

Wireless radio channels

IEEE 802.11a/n channels

The following table lists the channels supported on FortiWiFi products that support the IEEE 802.11a and 802.11n wireless standards. 802.11a is available on FortiWiFi models 60B and higher. 802.11n is available on FortiWiFi models 80CM and higher.

All channels are restricted to indoor usage except in the Americas, where both indoor and outdoor use is permitted on channels 52 through 64 in the United States.

IEEE 802.11a/n (5-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas				
		Americas	Europe	Taiwan	Singapore	Japan
34	5170					•
36	5180	•	•		•	
38	5190					
40	5200	•	•		•	•
42	5210					
44	5220	•	•		•	•
46	5230					
48	5240	•	•		•	•
149	5745	•		•	•	
153	5765	•		•	•	
157	5785	•		•	•	
161	5805	•		•	•	
165	5825	•			•	

IEEE 802.11b/g/n channel numbers

The following table lists IEEE 802.11b/g/n channels. All FortiWiFi units support 802.11b and 802.11g. Newer models also support 802.11n.

Mexico is included in the Americas regulatory domain. Channels 1 through 8 are for indoor use only. Channels 9 through 11 can be used indoors and outdoors. You must make sure that the channel number complies with the regulatory standards of Mexico.

IEEE 802.11b/g/n (2.4-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas			
		Americas	EMEA	Israel	Japan
1	2412	•	•	indoor	•
2	2417	•	•	indoor	•
3	2422	•	•	indoor	•
4	2427	•	•	indoor	•

12	2467		•	•	•
13	2472		•	•	•
14	2484				b only

FortiAP CLI

The FortiAP CLI controls radio and network operation through the use of variables manipulated with the `cfg` command. There are also diagnostic commands.

The cfg commands include the following:

`cfg -s`	List variables.
`cfg -a var=value`	Add or change a variable value.
`cfg -c`	Commit the change to flash.
`cfg -x`	Reset settings to factory defaults.
`cfg -r var`	Remove variable.
`cfg -e`	Export variables.
`cfg -h`	Display help for all commands.

The configuration variables are:

Var	Description and Values
BAUD_RATE	Console data rate: 9600, 19200, 38400, 57600, or 115200 baud.
WTP_NAME	By default, the name is the FortiAP serial number.
FIRMWARE_UPGRADE	Default is 0.
LOGIN_PASSWD	Administrator login password. By default this is empty.
ADMIN_TIMEOUT	Administrative timeout in minutes. Applies to Telnet and web-based manager sessions. Default is 5 minutes.
ADDR_MODE	How the FortiAP unit obtains its IP address and netmask. DHCP - FortiGate interface assigns address. STATIC - Specify in AP_IPADDR and AP_NETMASK. Default is DHCP.
AP_IPADDR AP_NETMASK IPGW	These variables set the FortiAP unit IP address, netmask and default gateway when ADDR_MODE is STATIC. Default 192.168.1.2 255.255.255.0, gateway 192.168.1.1.
AP_MODE	FortiAP operating mode. 0 - Thin AP (default) 2 - Unmanaged Site Survey mode. See SURVEY variables.
DNS_SERVER	DNS Server for clients. If ADDR_MODE is DHCP the DNS server is automatically assigned.
STP_MODE	Spanning Tree Protocol. 0 is off. 1 is on.
AP_MGMT_VLAN_ID	Non-zero value applies VLAN ID for unit management. Default: 0.
ALLOW_TELNET	0 (Telnet disable), 1 (Telnet enable), 2 (controlled by AC). 2 is default.
ALLOW_HTTP	0 (Http disable), 1 (Http enable), 2 (controlled by AC). 2 is default.

Var	Description and Values
AC_DISCOVERY_TYPE	1 - Static. Specify WiFi Controllers 2 - DHCP 3 - DNS 5 - Broadcast 6 - Multicast 0 - Cycle through all of the discovery types until successful.
AC_IPADDR_1 AC_IPADDR_2 AC_IPADDR_3	WiFi Controller IP addresses for static discovery.
AC_HOSTNAME_1 AC_HOSTNAME_2 AC_HOSTNAME_3	WiFi Controller host names for static discovery.
AC_DISCOVERY_MC_ADDR	Multicast address for controller discovery. Default 224.0.1.140.
AC_DISCOVERY_DHCP_OPTION_CODE	
	Option code for DHCP server. 138 (default)
AC_CTL_PORT	WiFi Controller control (CAPWAP) port. Default 5246.
AC_DATA_CHAN_SEC	Data channel security. 0 - Clear text 1 - DTLS (encrypted) 2 - Accept either DTLS or clear text (default)
MESH_AP_TYPE	Type of communication for backhaul to controller: 0 - Ethernet (default) 1 - WiFi mesh 2 - Ethernet with mesh backup support
MESH_AP_SSID	SSID for mesh backhaul. Default: fortinet.mesh.root

Var	Description and Values
MESH_AP_BSSID	WiFi MAC address
MESH_AP_PASSWD	Pre-shared key for mesh backhaul.
MESH_ETH_BRIDGE	1 - Bridge mesh WiFi SSID to FortiAP Ethernet port. This can be used for point-to-point bridge configuration. This is available only when MESH_AP_TYPE =1. 0 - No WiFi-Ethernet bridge (default).
MESH_MAX_HOPS	Maximum number of times packets can be passed from node to node on the mesh. Default is 4.
The following factors are summed and the FortiAP associates with the lowest scoring mesh AP.	
MESH_SCORE_HOP_WEIGHT	Multiplier for number of mesh hops from root. Default 50.
MESH_SCORE_CHAN_WEIGHT	AP total RSSI multiplier. Default 1.
MESH_SCORE_RATE_WEIGHT	Beacon data rate multiplier. Default 1.
MESH_SCORE_BAND_WEIGHT	Band weight (0 for 2.4GHz, 1 for 5GHz) multiplier. Default 100.
MESH_SCORE_RSSI_WEIGHT	AP channel RSSI multiplier. Default 100.
SURVEY_SSID	SSID to broadcast in site survey mode (AP_MODE=2).
SURVEY_TX_POWER	Transmitter power in site survey mode (AP_MODE=2).
SURVEY_CH_24	Site survey transmit channel for the 2.4Ghz band (default 6).
SURVEY_CH_50	Site survey transmit channel for the 5Ghz band (default 36).
SURVEY_BEACON_INTV	Site survey beacon interval. Default 100msec.
WTP_LOCATION	Optional string describing AP location.

Diagnose commands include:

`cw_diag help`	Display help for all diagnose commands.
`cw_diag uptime`	Show daemon uptime.
`cw_diag --tlog <on|off>`	Turn on/off telnet log message.
`cw_diag --clog <on|off>`	Turn on/off console log message.
`cw_diag baudrate [9600 | 19200 | 38400 | 57600 | 115200]`	Set the console baud rate.
`cw_diag plain-ctl [0|1]`	Show or change current plain control setting.
`cw_diag sniff-cfg ip port`	Set sniff server ip and port.
`cw_diag sniff [0|1|2]`	Enable/disable sniff packet.
`cw_diag stats wl_intf`	Show wl_intf status.
`cw_diag admin-timeout [30]`	Set shell idle timeout in minutes.
`cw_diag -c wtp-cfg`	Show current wtp config parameters in control plane.
`cw_diag -c radio-cfg`	Show current radio config parameters in control plane.
`cw_diag -c vap-cfg`	Show current vaps in control plane.
`cw_diag -c ap-rogue`	Show rogue APs pushed by AC for on-wire scan.
`cw_diag -c sta-rogue`	Show rogue STAs pushed by AC for on-wire scan.
`cw_diag -c arp-req`	Show scanned arp requests.
`cw_diag -c ap-scan`	Show scanned APs.
`cw_diag -c sta-scan`	Show scanned STAs.
`cw_diag -c sta-cap`	Show scanned STA capabilities.
`cw_diag -c wids`	Show scanned WIDS detections.
`cw_diag -c darrp`	Show darrp radio channel.
`cw_diag -c mesh`	Show mesh status.
`cw_diag -c mesh-veth-acinfo`	Show mesh veth ac info, and mesh ether type.
`cw_diag -c mesh-veth-vap`	Show mesh veth vap.

`cw_diag -c mesh-veth-host`	Show mesh veth host.
`cw_diag -c mesh-ap`	Show mesh ap candidates.
`cw_diag -c scan-clr-all`	Flush all scanned AP/STA/ARPs.
`cw_diag -c ap-suppress`	Show suppressed APs.
`cw_diag -c sta-deauth`	De-authenticate an STA.

Chapter 9 - Firewall

"Firewall concepts" explains the ideas behind the components, techniques and processes that are involved in setting up and running a firewall in general, and the FortiGate firewall in particular. Regardless of how experienced someone is with firewalls, as they go through the process of configuring a firewall new to them they are likely to come across a term or setting that they may not be familiar with. FortiGate firewalls are quite comprehensive and can be very granular in the functions they perform, so it makes sense to have a consistent frame of reference for the ideas we will be working with.

Some examples of the concepts that will be addressed here are:

- "What is a Firewall?"
- "NAT"
- "IPv6"

"Firewall objects" describes the following:

- Addressing
- Services
- Firewall Policies

"Network defense" describes various methods of defending your network using the abilities of the FortiGate firewall.

"GUI and CLI - what you may not know" helps you navigate and find the components in the Web-based Manager that you will need to build the functions. This section does not include any in-depth explanations of what each object does as that is covered in the concepts section. This section is for showing you where you need to input your information and letting you know what format the interface expects to get that information

"Building firewall objects and policies" is similar to a cookbook in that it will refer to a number of common tasks that you will likely perform to get the full functionality out of your FortiGate firewall. Because of the way that firewalls are designed, performing many of the tasks requires that firewall components be set up in a number of different sections of the interface and be configured to work together to achieve the desired result. This section will bring those components together as a straight forward series of instructions.

"Multicast forwarding" is a reference guide including the concepts and examples that are involved in the use of multicast addressing and policy forwarding as it is used in the FortiGate firewall.

FortiGate Firewall Components

The FortiGate firewall is made up of a number of different components that are used to build an impressive list of features. These features have flexibility of scope and granularity of control that provide protection far beyond that provided by the basic firewalls of the past.

Some of the components that FortiOS uses to build features are:

- Interfaces
- VLANs
- Soft switches

- Zones
- Predefined addresses
  - IP address-based
  - FQDN-based
  - Geography-based
- Access schedules
- Authentication
  - Local user-based
  - Authentication server-based (Active Directory, RADIUS, LDAP)
  - Device-based
- Configurable services
- IPv4 and IPv6 protocol support

The features of FortiOS include but are not limited to:

- Security profiles, sometimes referred to as Unified Threat Management (UTM) or Next Generation Firewall (NGFW)
- Predefined firewall addresses (this includes IPv4 and IPv6, IP pools, wildcard addresses and netmasks, and geography-based addresses)
- Monitoring traffic
- Traffic shaping and per-IP traffic shaping (advanced)
- Firewall schedules
- Services (such as AOL, DHCP and FTP)
- Logging traffic
- Quality of Service (QoS)
- Identity-based policies
- Endpoint security

The "Firewall concepts" expand on what each of the features does and how they relate to the administration of the FortiGate firewall. The section will also try to explain some of the common firewall concepts that will be touched on in the implementing of these features.

"Building firewall objects and policies" shows how to perform specific tasks with the FortiGate firewall.

How does a FortiGate protect your network?

The FortiGate firewall protects your network by taking the various components and using them together to build a kind of wall or access control point so anyone that is not supposed to be on your network is prevented from accessing your network in any way other than those approved by you. It also protects your network from itself by keeping things that shouldn't happen from happening and optimizing the flow of traffic so the network is protected from traffic congestion that would otherwise impede traffic flow.

Most people have at one time or another played with a child's toy system made up of interlocking blocks. The blocks come in different shapes and sizes so you can build structures to suit your needs. The components of the FortiGate firewall are similar. You are not forced to use all of the blocks all of the time. You mix and match them to get the results that you are looking for. You can build a very basic structure, where its only function is to direct traffic in and out to the correct subnets. You can build a fortress that only allows specific traffic to or from specific hosts at specific times of day and only when credentials that have been pre-approved have been provided. You can also add in that all of the traffic is encrypted, so that even when the traffic is out on the Internet it is private

from the world. Just like the interlocking blocks, what you build is up to you, but chances are if you put them together the right way there isn't much that can't be built.

Here is one example of how the components could be put together to support the requirements of a network infrastructure design.

- Off the internal interface you could have separate VLANs. One for each department of Sales, Marketing and Engineering so the traffic from the users on one VLAN does not intrude upon the hosts of the other VLANs and each department is isolated from the others for security reasons.
- To ease in the administration, each of the VLAN sub-interfaces is made a member of a zone so security policies that apply to all hosts on all the VLANs can be applied to all of them at once.
- Using the addresses component, each of the IP address ranges could be assigned a user-friendly name so they could be referred to individually. For policies that would refer to them all as a whole, the individual ranges can be made members of an address group.
- Firewall schedules could be created to address the differing needs of each of the groups so that Sales and Marketing could be allowed access to the Internet during regular business hours and the Engineering department could be allowed access during the lunch break.
- By setting up the outgoing policies to use FortiGuard Web-filtering, the employees could be prevented from visiting inappropriate sites and thus enforcing the policies of the HR department.
- A couple of virtual IP addresses with port forwarding could be configured to allow users on the Internet access to a web server on the DMZ subnet using the company's only Public IP address.This would not affect the traffic that goes to the company's mail server hosted on a completely different computer.
- Even though the Web server on the same DMZ has an FTP service to allow for the uploading of web pages to the web server from the Marketing and Engineer teams, by placing a DENY policy on any FTP traffic from the Internet, malicious users are prevented from abusing the FTP service.
- By monitoring the traffic as it goes through the policies, you can verify that the policies are in working order.
- By using a combination of ALLOW and DENY policies and placing them in the correct order, you could arrange for an outside contractor to be allowed to update the web site as well.

This list of possible configurations is not extensive, but it does give an idea of how different components can be mixed and matched to build a configuration that meets an organization's needs and at the same time protect it from security risks.

Firewall concepts

There are a number of concepts that are consistent throughout the firewall industry. Having a solid grasp of these ideas and terms can give you a better idea of what your FortiGate firewall is capable of and how it will fit within your network's architecture.

This chapter describes the following firewall concepts:

- What is a Firewall?
- IPv6
- NAT
- How packets are handled by FortiOS
- FortiGate modes
- Quality of Service
- Interfaces and zones

What is a firewall?

The term firewall originally referred to a wall intended to confine a fire or potential fire within a building. Later uses refer to similar structures, such as the metal sheet separating the engine compartment of a vehicle or aircraft from the passenger compartment.

A firewall can either be software-based or hardware-based and is used to help keep a network secure. Its primary objective is to control the incoming and outgoing network traffic by analyzing the data packets and determining whether it should be allowed through or not, based on a predetermined rule set. A network's firewall builds a bridge between an internal network that is assumed to be secure and trusted, and another network, usually an external (inter)network such as the Internet, that is not assumed to be secure and trusted.

Network layer or packet filter firewalls

Stateless firewalls

Stateless firewalls are the oldest form of these firewalls. They are faster and simple in design requiring less memory because they process each packet individually and don't require the resources necessary to hold onto packets like stateful firewalls. Stateful firewalls inspect each packet individually and check to see if it matches a predetermined set of rules. According to the matching rule, the packet is either allowed, dropped or rejected. In the case of a rejection, an error message is sent to the source of the traffic. Each packet is inspected in isolation and information is only gathered from the packet itself. Simply put, if the packets were not specifically allowed according to the list of rules held by the firewall, they were not getting through.

Stateful firewalls

Stateful firewalls retain packets in memory so that they can maintain context about active sessions and make judgments about the state of an incoming packet's connection. This enables Stateful firewalls to determine if a packet is the start of a new connection, a part of an existing connection, or not part of any connection. If a packet is part of an existing connection based on comparison with the firewall's state table, it will be allowed to pass without further processing. If a packet does not match an existing connection, it will be evaluated according to the

rules set for new connections. Predetermined rules are used in the same way as a stateless firewall but they can now work with the additional criteria of the state of the connection to the firewall.

Best Practices Tip for improving performance:

Blocking the packets in a denied session can take more cpu processing resources than passing the traffic through. By putting denied sessions in the session table, they can be kept track of in the same way that allowed session are so that the FortiGate unit does not have to redetermine whether or not to deny all of the packets of a session individually. If the session is denied all packets of that session are also denied.

In order to configure this you will need to use 2 CLI commands

```
config system setting
     set ses-denied-traffic enable
     set block-session-timer <integer 1 - 300>
```
(this determines in seconds, how long, the session is kept in the table)
```
end
```

Application layer firewalls

Application layer filtering is yet another approach and as the name implies it works primarily on the Application Layer of the OSI Model.

Application Layer Firewalls actually, for lack of a better term, understand certain applications and protocols. Examples would be FTP, DNS and HTTP. This form of filtration is able to check to see if the packets are actually behaving incorrectly or if the packets have been incorrectly formatted for the protocol that is indicated. This process also allows for the use of deep packet inspection and the sharing of functionality with Intrusion Prevention Systems (IPS).

Application-layer firewalls work on the application level of the TCP/IP stack (i.e., all browser traffic, or all telnet or ftp traffic), and may intercept all packets traveling to or from an application. They block other packets (usually dropping them without acknowledgment to the sender). Application firewalls work much like a packet filter but application filters apply filtering rules (allow/block) on a per process basis instead of filtering connections on a per port basis.

On inspecting all packets for improper content, firewalls can restrict or prevent outright the spread of networked computer worms and trojans. The additional inspection criteria can add extra latency to the forwarding of packets to their destination.

Proxy servers

A proxy server is an appliance or application that acts as an intermediary for communicating between computers. A computer has a request for information. The packets are sent to the designated resource but before they can get there they are blocked by the proxy server saying that it will take the request and pass it on. The Proxy Server processes the request and if it is valid it passes onto the designated computer. The designated computer gets the packet and processes the request, sending the answer back to the proxy server. The proxy server sends the information back to the originating computer. It's all a little like a situation with two people who refuse to talk directly with each other using someone else to take messages back and forth.

From a security stand point a Proxy Server can serve a few purposes:

- Protects the anonymity of the originating computer
- The two computers never deal directly with each other
- Packets that are not configured to be forwarded are dropped before reaching the destination computer.
- If malicious code is sent it will affect the Proxy server with out affecting the originating or sending computer.

Proxies can perform a number of roles including:

- Content Filtering
- Caching
- DNS proxy
- Bypassing Filters and Censorship
- Logging and eavesdropping
- Gateways to private networks
- Accessing service anonymously

Security profiles

Unified Threat Management and Next Generation Firewall are terms originally coined by market research firms and refer to the concept of a comprehensive security solution provided in a single package. It is basically combining of what used to be accomplished by a number of different security technologies all under a single umbrella or in this case, a single device. On the FortiGate firewall this is achieved by the use of Security Profiles and optimized hardware.

In effect it is going from a previous style of firewall that included among its features:

- Gateway Network Firewall
- Routing
- VPN

To a more complete system that includes:

- Gateway Network Firewall
- Routing
- VPN
- Traffic Optimization
- Proxy Services
- Content Filtering
- Application Control
- Intrusion Protection
- Denial of Service Attack Protection
- Anti-virus
- Anti-spam
- Data Leak Prevention
- Endpoint Control of Security Applications
- Load Balancing
- WiFi Access Management
- Authentication Integration into Gateway Security

- Logging
- Reporting

Advantages of using security profiles

- Avoidance of multiple installations.
- Hardware requirements are fewer.
- Fewer hardware maintenance requirements.
- Less space required.
- Compatibility - multiple installations of products increase the probability of incompatibility between systems.
- Easier support and management.
- There is only one product to learn therefore a reduced requirement of technical knowledge.
- Only a single vendor so there are fewer support contracts and Service Level Agreements.
- Easier to incorporated into existing security architecture.
- Plug and play architecture.
- Web based GUI for administration.

IPv6

Internet Protocol version 6 (IPv6) will succeed IPv4 as the standard networking protocol of the Internet. IPv6 provides a number of advances over IPv4 but the primary reason for its replacing IPv4 is its limitation in addresses. IPv4 uses 32 bit addresses which means there is a theoretical limit of 2 to the power of 32. The IPv6 address scheme is based on a 128 bit address or a theoretical limit of 2 to the power of 128.

Possible Addresses:

- IPv4 = 4,294,967,296 (over 4 billion)
- IPv6 = 340,282,366,920,938,463,463,374,607,431,768,211,456 (over 340 undecillion - We had to look that term up. We didn't know what a number followed by 36 digits was either)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices.

There is little likelihood that you will ever need to worry about these numbers as any kind of serious limitation in addressing but they do give an idea of the scope of the difference in the available addressing.

Aside from the difference of possible addresses there is also the different formatting of the addresses that will need to be addressed.

A computer would view an IPv4 address as a 32 bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period "."

Example:

10101100.00010000.11111110.00000001

To make number more user friendly for humans we translate this into decimal, again 4 octets separated by a period "."which works out to:

172.16.254.1

A computer would view an IPv6 address as a 128 bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon ":"

1000000000000001:0000110110111000:1010110000010000:1111111000000001:0000000000000000:0000000000000000:0000000000000000:0000000000000000

To make number a little more user friendly for humans we translate this into hexadecimal, again 8 octets separated by a colon ":" which works out to:

8001:0DB8:AC10:FE01:0000:0000:0000:0000:

Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, this address can be shortened further to:

8001:0DB8:AC10:FE01:0:0:0:0

or

8001:0DB8:AC10:FE01::

Some of the other benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local and global address space

The origins of NAT

In order to understand NAT it helps to know why it was created. At one time, every computer that was part of a network had to have it's own addresses so that the other computers could talk to it. There were a few protocols in use at the time, some of which were only for use on a single network, but of those that were routable, the one that had become the standard for the Internet was IP (Internet Protocol) version 4.

When IP version 4 addressing was created nobody had any idea how many addresses would be needed. The total address range was based on the concept of 2 to the 32nd power, which works out to be 4 294 967 296 potential addresses. Once you eliminate some of those for reserved addresses, broadcast addresses, network addresses, multicasting, etc., you end up with a workable scope of about 3.2 million addressees. This was thought to be more than enough at the time. The designers were not expecting the explosion of personal computing, the World Wide Web or smart phones. As of the beginning of 2012, some estimate the number of computers in the world in the neighborhood of 1 billion, and most of those computer users are going to want to be on the Internet or Search the World Wide Web. In short, we ran out of addresses.

This problem of an address shortage was realized before we actually ran out, and in the mid 1990s 2 technical papers called RFCs numbered 1631 (http://www.ietf.org/rfc/rfc1631.txt) and 1918 (http://tools.ietf.org/html/rfc1918), proposed components of a method that would be used as a solution until a new addressing methodology could be implemented across the Internet infrastructure. For more information on this you can look up IP version 6.

RFC 1631 described a process that would allow networking devices to translate a single public address to multiple private IP addresses and RFC 1918 laid out the use of the private addresses. The addresses that were

on the Internet (Public IP addresses) could not be duplicated for them to work as unique addresses, but behind a firewall, which most large institutions had, they could use their own Private IP addresses for internal use and the internal computers could share the external or Public IP address.

To give an idea on a small scale how this works, image that a company has a need for 200 computer addresses. Before Private IP addresses and NAT the company would have purchased a full Class C address range which would have been 254 usable IP addresses; wasting about 50 addresses. Now with NAT, that company only needs 1 IP address for its 200 computers and this leaves the rest of the IP addresses in that range available for other companies to do the same thing.

NAT gives better value than it would first appear because it is not 253 companies that can use 254 addresses but each of those 254 companies could set up their networking infrastructures to use up to thousands of Private IP addresses, more if they don't all have to talk to the Internet at the same time. This process enabled the Internet to keep growing even though we technically have many more computers networked than we have addresses.

Static NAT

In Static NAT one internal IP address is always mapped to the same public IP address.

In FortiGate firewall configurations this is most commonly done with the use of Virtual IP addressing.

An example would be if you had a small range of IP addresses assigned to you by your ISP and you wished to use one of those IP address exclusively for a particular server such as an email server.

Say the internal address of the Email server was 192.168.12.25 and the Public IP address from your assigned addresses range from 256.16.32.65 to 256.16.32.127. Many readers will notice that because one of the numbers is above 255 that this is not a real Public IP address. The Address that you have assigned to the interface connected to your ISP is 256.16.32.66, with 256.16.32.65 being the remote gateway. You wish to use the address of 256.16.32.70 exclusively for your email server.

When using a Virtual IP address you set the external IP address of 256.16.32.70 to map to 192.168.12.25. This means that any traffic being sent to the public address of 256.16.32.70 will be directed to the internal computer at the address of 192.168.12.25

When using a Virtual IP address, this will have the added function that when ever traffic goes from 192.168.12.25 to the Internet it will appear to the recipient of that traffic at the other end as coming from 256.16.32.70.

You should note that if you use Virtual IP addressing with the Port Forwarding enabled you do not get this reciprocal effect and must use IP pools to make sure that the outbound traffic uses the specified IP address.

Dynamic NAT

Dynamic NAT maps the private IP addresses to the first available Public Address from a pool of possible Addresses. In the FortiGate firewall this can be done by using IP Pools.

Overloading

This is a form of Dynamic NAT that maps multiple private IP address to a single Public IP address but differentiates them by using a different port assignment. This is probably the most widely used version of NAT. This is also referred to as PAT (Port Address Translation) or Masquerading.

An example would be if you had a single IP address assigned to you by your ISP but had 50 or 60 computers on your local network.

Say the internal address of the interface connected to the ISP was 256.16.32.65 (again an impossible address) with 256.16.32.64 being the remote gateway. If you are using this form of NAT any time one of your computers accesses the Internet it will be seen from the Internet as 256.16.32.65. If you wish to test this go to 2 different computers and verify that they each have a different private IP address then go to a site that tells you your IP address such as www.ipchicken.com. You will see that the site gives the same result of 256.16.32.65, if it existed, as the public address for both computers.

As mentioned before this is sometimes called Port Address Translation because network device uses TCP ports to determine which internal IP address is associated with each session through the network device. For example, if you have a network with internal addresses ranging from 192.168.1.1 to 192.168.1.255 and you have 5 computers all trying to connect to a web site which is normally listening on port 80 all of them will appear to the remote web site to have the IP address of 256.16.32.65 but they will each have a different sending TCP port, with the port numbers being somewhere between 1 and 65 535, although the port numbers between 1 to 1024 are usually reserved or already in use. So it could be something like the following:

```
192.168.1.10    256.16.32.65:   port 486
192.168.1.23    256.16.32.65:   port 2409
192.168.1.56    256.16.32.65:   port 53763
192.168.1.109   256.16.32.65:   port 5548
192.168.1.201   256.16.32.65:   port 4396
```

And the remote web server would send the responding traffic back based on those port numbers so the network device would be able to sort through the incoming traffic and pass it on to the correct computer.

Overlapping

Because everybody is using the relative same small selection of Private IP addresses it is inevitable that there will be two networks that share the same network range that will need to talk with each other. This happens most often over Virtual Private Networks or when one organization ends up merging with another. This is a case where a private IP address may be translated into a different private IP address so there are no issues with conflict of addresses or confusion in terms of routing.

An example of this would be when you have a Main office that is using an IP range of 172.16.0.1 to 172.20.255.255 connecting through a VPN to a recently acquired branch office that is already running with an IP range of 172.17.1.1 to 172.17.255.255. Both of these ranges are perfectly valid but because the Branch office range is included in the Main Office range any time the system from the Main office try to connect to an address in the Branch Office the routing the system will not send the packet to the default gateway because according to the routing table the address is in its own subnet.

The plan here would be to NAT in both directions so that traffic from neither side of the firewall would be in conflict and they would be able to route the traffic. Everything coming from the Branch Office could be assigned an address in the 192.168.1.1 to 192.168.1.255 range and everything from the Main office going to the Branch Office could be assigned to an address in the 192.168.10.1 to 192.168.10.255 range.

Benefits of NAT

More IP addresses available while conserving public IP addresses

As explained earlier, this was the original intent of the technology and does not need to be gone into further.

Financial savings

Because an organization does not have to purchase IP addresses for every computer in use there is a significant cost savings due to using the process of Network Address Translation.

Security enhancements

One of the side benefits of the process of NAT is an improvement in security. Individual computers are harder to target from the outside and if port forwarding is being used computers on the inside of a firewall are less likely to have unmonitored open ports accessible from the Internet.

Ease of compartmentalization of your network

With a large available pool of IP addresses to use internally a network administrator can arrange things to be compartmentalized in a rational and easily remembered fashion and networks can be broken apart easily to isolate for reasons of network performance and security.

Example

You have a large organization that for security reasons has certain departments that do not share network resources.

You can have the main section of the organization set up as follows;

Network Devices	192.168.1.1 to 192.168.1.25
Internal Servers	192.168.1.26 to 192.168.1.50
Printers	192.168.1.51 to 192.168.1.75
Administration Personnel	192.168.1.76 to 192.168.1.100
Sales People	192.168.1.101 to 192.168.1.200
Marketing	192.168.1.201 to 192.168.1.250

You could then have the following groups broken off into separate subnets:

Accounting	192.168.100.1 to 192.168.100.255
Research and Development	172.16.1.1 to 172.16.255.255
Executive Management	192.168.50.1 to 192.168.50.255
Web sites and Email Servers	10.0.50.1 to 10.0.50.255

These addresses do not have to be assigned right away but can be used as planned ranges.

NAT in transparent mode

Similar to operating in NAT mode, when operating a FortiGate unit in Transparent mode you can add security policies and:

- Enable NAT to translate the source addresses of packets as they pass through the FortiGate unit.
- Add virtual IPs to translate destination addresses of packets as they pass through the FortiGate unit.
- Add IP pools as required for source address translation

A FortiGate unit operating in Transparent mode normally has only one IP address - the management IP. To support NAT in Transparent mode, you can add a second management IP. These two management IPs must be on different subnets. When you add two management IP addresses, all FortiGate unit network interfaces will respond to connections to both of these IP addresses.

Use the following steps to configure NAT in Transparent mode:

1. Add two management IPs
2. Add an IP pool to the WAN1 interface
3. Add an Internal to WAN1 security policy

You can add the security policy from the web-based manager and then use the CLI to enable NAT and add the IP pool.

The usual practice of NATing in transparent mode makes use of two management IP addresses that are on different subnets, but this is not an essential requirement in every case.

If there is a router between the client systems and the FortiGate unit you can use the router's capabilities of tracking sessions to assign NATed addresses from an IP pool to the clients even if the assigned address don't belong to a subnet on your network.

Example

Client computer has an IP address of 1.1.1.33 on the subnet 1.1.1.0/24.

Router "A" sits between the client computer and the FortiGate (in Transparent mode) with the IP address of 1.1.1.1 on the client's side of the router and the IP address of 192.168.1.211 on the FortiGate's side of the router.

Use NAT to assign addresses from an address pool of 9.9.9.1 to 9.9.9.99 to traffic coming from gateway of 192.168.1.211.

To enable the return traffic to get to the original computer, set up a static route than assigns any traffic with a destination of 9.9.9.0/24 to go through the 192.168.1.211 gateway. As long as the session for the outgoing traffic has been maintained, communication between the client computer and the external system on the other side of the FortiGate will work.

.

Central NAT table

The central NAT table enables you to define, and control with more granularity, the address translation performed by the FortiGate unit. With the NAT table, you can define the rules which dictate the source address or address group and which IP pool the destination address uses.

While similar in functionality to IP pools, where a single address is translated to an alternate address from a range of IP addresses, with IP pools there is no control over the translated port. When using the IP pool for source NAT, you can define a fixed port to guarantee the source port number is unchanged. If no fix port is defined, the port translation is randomly chosen by the FortiGate unit. With the central NAT table, you have full control over both the IP address and port translation.

The FortiGate unit reads the NAT rules in a top-down methodology, until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on the source

address. The NAT policies can be rearranged within the policy list as well. NAT policies are applied to network traffic after a security policy.

IPv6 in FortiOS

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use IPv6 format for addresses. There is also no need for NAT if the FortiGate firewall is the interface between IPv6 networks. If the subnets attached to the FortiGate firewall are IPv6 and IPv4 NAT can be configured between the 2 different formats. This will involve either configuring a dual stack routing or IPv4 tunneling configuration. The reason for this is simple. NAT was developed primarily for the purpose of extending the number of usable IPv4 addresses. IPv6's addressing allows for enough available addresses so the NAT is no longer necessary.

When configuring IPv6 in FortiOS, you can create a dual stack route or IPv4-IPv6 tunnel. A dual stack routing configuration implements dual IP layers, supporting both IPv4 and IPv6, in both hosts and routers. An IPv4-IPv6 tunnel is essentially similar, creating a tunnel that encapsulates IPv6 packets within IPv4 headers that carry these IPv6 packets over IPv4 tunnels. The FortiGate unit can also be easily integrated into an IPv6 network. Connecting the FortiGate unit to an IPv6 network is exactly the same as connecting it to an IPv4 network, the only difference is that you are using IPv6 addresses.

By default the IPv6 settings are not displayed in the Web-based Manager. It is just a matter of enabling the display of these feature to use them through the web interface. To enable them just go to **System > Admin > Settings** and select **IPv6 Support on GUI**. Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features:

- Static routing
- Policy Routing
- Packet and network sniffing
- Dynamic routing (RIPv6, BGP4+, and OSPFv3)
- IPsec VPN
- DNS
- DHCP
- SSL VPN
- Network interface addressing
- Security Profiles protection
- Routing access lists and prefix lists
- NAT/Route and Transparent mode
- NAT 64 and NAT 66
- IPv6 tunnel over IPv4 and IPv4 tunnel over IPv6
- Logging and reporting
- Security policies
- SNMP
- Authentication
- Virtual IPs and groups
- IPv6 over SCTP
- IPv6-specific troubleshooting, such as ping6

Dual stack routing configuration

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses. In the FortiOS dual stack architecture it is not just the basic addressing functions that operate in both versions of IP. The other features of the appliance such as Security Profiles and routing can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunneling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

IPv6 tunneling

IPv6 Tunneling is the act of tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than Network Address Translation (NAT) because once the packet reaches its final destination the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network. This type of configuration is more appropriate for those who have completely transitional over to IPv6, but need an Internet connection, which is still mostly IPv4 addresses.

The key to IPv6 tunneling is the ability of the 2 devices, whether they are a host or a network device, to be dual stack compatible. They have to be able to work with both IPv4 and IPv6 at the same time. In the process the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet. The IPv4 header is removed. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6:

Automatic tunnels	Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to.
Configured tunnels	Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel configurations

There are a few ways in which the tunneling can be performed depending on which segment of the path between the end points of the session the encapsulation takes place.

Network Device to Network Device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans one segment of the path taken by the IPv6 packets.
Host to Network Device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. This type of tunnel spans the first segment of the path taken by the IPv6 packets.
Host to Host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.
Network Device to Host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

Tunneling IPv6 through IPsec VPN

A variation on the tunneling IPv6 through IPv4 is using an IPsec VPN tunnel between to FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, 2 networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the 2 FortiGate units and a tunnel is created over the IPv4 based Internet but the traffic in the tunnel is IPv6. This has the additional advantage of make the traffic secure as well.

NAT

NAT or Network Address Translation is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This “agent”, in real time, translates the source IP address of a device on one network interface, usually the Internal, to a different IP address as it leaves another interface, usually the interface connected to the ISP and the Internet. This enables a single public address to represent a significantly larger number of private addresses.

NAT64 and NAT46

NAT64 and NAT46 are the terms used to refer to the mechanism that allows IPv6 addressed hosts to communicate with IPv4 addressed hosts and vice-versa. Without such a mechanism an IPv6 node on a network such as a corporate LAN would not be able to communicate with a web site that was still in a IPv4 only environment and IPv4 environments would not be able to connect to IPv6 networks.

One of these setups involves having at least 2 interfaces, 1 on an IPv4 network and 1 on an IPv6 network. The NAT64 server synthesizes AAAA records, used by IPv6 from A records used by IPv4. This way client-server and peer to peer communications will be able to work between an IPv6 only client and an IPv4 server without making changes to either of the end nodes in the communication transaction. The IPv6 network attached to the FortiGate unit should be a 32 bit segment, (for instance 64:ff9b::/96, see RFC 6052 and RFC 6146). IPv4 address will be embedded into the communications from the IPv6 client.

Because the IPv6 range of addresses is so much larger than the IPv4 range, a one to one mapping is not feasible. Therefore the NAT64 function is required to maintain any IPv6 to IPv4 mappings that it synthesizes. This can be done either statically by the administrator or automatically by the service as the packets from the IPv6 network go through the device. The first method would be a stateless translation and the second would be a stateful translation. NAT64 is designed for communication initiated from IPv6 hosts to IPv4 addresses. It is address mapping like this that allows the reverse to occur between established connections. The stateless or manual method is an appropriate solution when the NAT64 translation is taking place in front of legacy IPv4 servers to allow those specific servers to be accessed by remote IPv6-only clients. The stateful or automatic solution is best used closer to the client side when you have to allow some specific IPv6 clients to talk to any of the IPv4-only servers on the Internet.

There are currently issues with NAT64 not being able to make everything accessible. Examples would be SIP, Skype, MSN, Goggle talk, and sites with IPv4 literals. IPv4 literals being IPv4 addresses that are imbedded into content rather than a FQDN.

Policies that employ NAT64 or NAT46 can be configured from the web-based manager as long as the feature is enabled using the Features setting found at **System > Config > Features**.

- To create a NAT64 policy go to **Policy > Policy > NAT64 Policy** and select **Create New**.
- To create a NAT46 policy go to **Policy > Policy > NAT46 Policy** and select **Create New**.

The difference between these NAT policies and regular policies is that there is no option to use the security profiles and sensors.

NAT66

NAT 66 is Network Address Translation between 2 IPv6 network. The basic idea behind NAT 66 is no different than the regular NAT between IPv4 networks that we are all used to. The difference are in the mechanics of how it is performed, mainly because of the complexity and size of the addresses that are being dealt with.

In an IPv4 world, the reason for the use of NAT was usually one or a combination of the following 3 reasons:

- Improved security - actual addresses behind NAT are virtually hidden
- Amplification of addresses - hundreds of computers can use as little as a single public IP address
- Internal address stability - there is control of internal addressing. The addresses can stay the same even if Internet Service Providers change.

In these days of security awareness the protective properties of NAT are not something that are not normally depended on by themselves to defend a network and with the vastly enlarged IPv6 address scope there is no longer a need to amplify the available addresses. However, the desire to have internal address control still exists. The most common reason for using NAT66 is likely to be the maintaining of the existing address scheme of the internal network despite changes outside of it. Imagine that you have an internal network of 2000 IP addresses and one day the company changes its ISP and thus the addresses assigned to it. Even if most of the addressing is handled by DHCP, changing the address scheme is going to have an impact on operations.

Addressing stability can be achieved by:

- Keeping the same provider - this would depend on the reason for the change. If the cost of this provider has become too expensive this is unlikely. If the ISP is out of business it becomes impossible.
- Transfer the addresses from the old provider to the new one - There is little motivation for an ISP to do you a favor for not doing business with them.
- Get your own autonomous system number - this can be too expensive for smaller organizations.
- NAT - this is the only one on the list that is in the control of IT.

There are differences between NAT66 and IPv4 NAT. Because there is no shortage of addresses most organizations will be given a /48 network that can be translated into another /48 network. This allows for a one to one translation, no need for port forwarding. This is a good thing because port forwarding is more complicated in IPv6. In fact, NAT66 will actually just be the rewriting of the prefix on the address.

Example

If your current IPv6 address is

```
2001:db8:cafe::/48
```

you could change it to

```
2001:db8:fea7::/48
```

There is an exception to the one to one translation. NAT66 cannot translate internal networks that contain 0xffff in bits 49 through 63 - this is due to the way checksums are calculated in TCP/IP: they use the one's-complement representation of numbers which assigns the value zero to both 0x0000 and 0xffff.

How FortiOS differentiates sessions when NATing

The basics of NAT are fairly simple. Many private addresses get translated into a smaller number of public addresses, often just one. The trick is how the FortiGate keeps track of the return traffic because the web server, or what ever device that was out on the Internet is going to be sending traffic back not to the private address behind the FortiGate but to the IP address of the interface on the public side of the FortiGate.

The way this is done is by making each session unique. Most of the attributes that are available in the network packets cannot be changed without changing where the packet will go but because the source port has to be changed anyway in case two computer on the network used the same source port this is a useful way of making each listing of network attributes a unique combination. As a packet goes through the NAT process FortiOS assigns different source ports for each of the internally initiated sessions and keeping track of which port was used for each device in a database until the session has ended. It then becomes a matter of how the port number is selected.

In a very simple example of an environment using NAT, we will use a fictitious university with a rather large student population. So large in fact that they use a subnet of `10.0.0.0/8` as their subnet for workstation IP addresses. All of these private IP addresses are NATed out a single IP address. To keep the number of numeric values in this example from getting to a confusing level, we'll just us "`u.u.u.1`" to refer to the public IP address of the University and the IP address of the web server on the Internet will be "`w.w.w.1`".

Student A (IP address `10.1.1.56`) sends an HTML request to a web server on the Internet with the IP address `w.w.w.1`. The applicable networking information in the packet breaks down as follows:

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	`10.1.1.56`	`u.u.u.1`
Destination IP address or dst-ip:	`w.w.w.1`	`w.w.w.1`
Source port or src-port:	10000	**46372**
Destination port or dst-port	80	80

The source IP address is now that of the public facing interface of the FortiGate and source port number is an unused TCP port number on the FortiGate chosen by the FortiGate. Of these variable the only one the that FortiGate can really change and still have the packet reach the correct destination, in both directions, is the source port number.

There are a few methods of assigning the port number. First we'll look at the methods that are or have been used in the industry but aren't used by Fortinet.

Global pool

This method of differentiation focuses on the attribute of the source port number. In this approach a single pool of potential port numbers is set aside for the purposes of NAT. As a pool number is assigned, it is removed from the pool so that two sessions from different computers can not using the same port number. Once the session is over and no longer in use by the computer, the port number is put back into the pool where it can be assigned again.

Example global pool:

	Hexidecimal	Decimal
Start or range	0x7000	28672
End end of range	0xF000	61440
Possible ports in range	215	32768

This is a simple approach to implement and is good if the number of connections in unlike to reach the pool size. It would be okay for home use, but our example is for a university using `10.1.1.0/8` as a subnet. That means 16,777,214 possible IP addresses; more than this method can handle.

Fortinet does not use this method.

Global per protocol

This method uses the attributes source port number and type of protocol to differentiate between sessions.This approach is a variation of the first one. An additional piece of information is refered to in the packet that describes the protocol. For instance UDP or TCP. This could effectively double the number of potential addresses to NAT.

Example:

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	**46372**
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	udp	udp
Source port or src-port:	26785	**46372**
Destination port or dst-port	80	80

Even though the source port is the same, because the protocol is different they are considered to be from different sessions and different computers.

The drawback is that it would depend on the protocols being used be evenly distributed between TCP and UDP. Even if this was the case the number would only double; reaching an upper limit of 65,536 possible connections. That number is still far short of the possible more than 16 million for an IP subnet with an eight bit subnet mask like the one in our example.

Fortinet does not use this method.

Per NAT IP Pool

This approach adds on to the previous one by adding another variable. In this case that variable is the IP addresses on the public side of the FortiGate. By having a pool of IP addresses to assign as the source IP address when NATing, the same number that was potentially available for the Global per protocol method can be multiplied by the number of external IP addresses in the pool. If you can assign a second IP address to the pool, you can double the potential number of sessions.

Example:

In this example it will be assumed that the FortiGate has 2 IP addresses that it can use. This could happen either by using two ISPs, or by having a pool of IP addresses assigned to a single interface. For simplicity will will refer

to these IP public IP addresses as `u.u.u.1` and `u.u.u.2`.

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	`10.1.1.56`	`u.u.u.1`
Destination IP address or dst-ip:	`w.w.w.1`	`w.w.w.1`
Protocol	tcp	tcp
Source port or src-port:	10000	**46372**
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	`10.5.1.233`	`u.u.u.2`
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	26785	**46372**
Destination port or dst-port	80	80

In this example we even made the protocl the same. After the NATing process all of the variables are the same except the sourse addresss. This is still going to make it bake to the original sender.

The drawback is that if you have only one IP address for the purposes of NATing this method does not gain you anything over the last method. Or if you do have multiple IP addresses to use it will still take quite a few to reach the 16 million possible that the subnet is capable of handling.

Fortinet does not use this method.

Per NAT IP, destination IP, port, and protocol

This is the approach that FortiOS uses.

It uses all of the differentiation point of the previous methods, NAT IP, port number and protocol, but the additonal information point of the destination IP is also used. So now the network information points in the packet that the FortiGate keeps in its database to differentiate between sessions is:

- Public IP address of the FortiGate assigned by NATing
- Protocol of the traffic
- Source port assigned by the FortiGate
- Destination IP address of the packet

The last one is an especially good way to differentiate because as a theortical number, the upper limit on that is the numbers of Public IP addresses on the whole of the Internet. Chances are that while a large number of session from inside the University will be going to a small group of sites such as Google, Youtube, Facebook and some others it is unlikely that they will all be going to them at the same time.

Example:

In this example it will be assumed that the FortiGate has only one IP address.Two possible packets will be described. The only difference in the attributes recorded will be the destination of the HTML request.These packets are still considered to be from differnt sessions and any responses will make it back to the correct computer.

From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	**46372**
Destination port or dst-port	80	80

From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.2	w.w.w.2
Protocol	tcp	tcp
Source port or src-port:	26785	**46372**
Destination port or dst-port	80	80

The reason that these attributes are used to determine defferentiation between traffic is based on how the indexes for the sessions are recorded in the database. When a TCP connection is made through a FortiGate unit, a session is created and two indexes are created for the session. The FortiGate unit uses these indexes to guide matching traffic to the session.

This following could be the session record for the TCP connection in the first example.

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	80
Destination port	80	46372 (FortiGate assigned port)

Using the FortiGate's approach for session differentiation, FortiOS only has to ensure that the assigned port, along with the other four attributes is a unique combination to identify the session. So for example, if Student A simultaneously makes a HTTP(port 80) connection and a HTTPS(port 443) connection the same web server this would create another session and the index in the reply direction would be:

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	443
Destination port	443	46372 (FortiGate assigned port)

These two sessions are different and acceptable because of the different source port numbers on the returning traffic or the destination port depending on the direction of the traffic.

Calculations for possible session numbers

The result of using these four attributes instead of just the one that was originally used is a large increase in the number of possible unique combinations.For those who love math, the maximum number of simultaneous connections that can be supported is:

N x R x P x D x Dp

where:

- **N** is the number of NAT IP addresses
- **R** is the port range,
- **P** is the number of protocols,
- **D** is the number of unique destination IP addresses
- **Dp** the number of unique destination ports.

As a rough example let's do some basic calculations

- N - In our existing example we have already stated that there is only one public IP address that is being used by NAT. Realistically, for a university this number would likely be larger, but we're keeping it simple.

  N = 1

R - The port range for our example has already been describe and we will keep it the same.

R = 32768

P - While there are a few protocols that are involved in Internet traffic we will limit this calculation just to TCP traffic.

P = 1

D - As mentioned before the number of unique destination addresses is growing larger every day,so figureing out the upper limit of that numbe would be difficult to say the least. Instead we will make the assumption that most of the university students, do to their shared interest and similar demographic will concentrate most of their web browsing to the same sites; sites such as YouTube, Facebook, Google, Twitter, Instagram, Wikipedia etc. This is not even taking into account the fact that many of these popular sites use load balancing and multiple IP addresses. As an arbatrary number let's use the number 25.

D = 25

Dp - To keep things simple it is tempting to limit the destiation port to port 80, the one that many associate with web browsing, but this would not be realistic. the use of HTTPS, port 443 is on the rise. There is also email, DNS, FTP, NTP and a number of other background services that we use without thinking too closely about. Let's keep it small and say ten of them.

Dp = 10

The math on this very conservative calculation is:

1 x 32768 x 1 x 25 x 10 = 8,192,000 possible NAT sessions

When you take into account that the chances of everybody being online at the same time, going only to one of those 25 sites and not millions of others, and using only TCP not UDP or any of the other protocols, it starts to look like this method may provide enough potential unique sessions even for a subnet as large as the one described.

How packets are handled by FortiOS

To give you idea of what happens to a packet as it makes its way through the FortiGate unit here is a brief overview. This particular trip of the packet is starting on the Internet side of the FortiGate firewall and ends with the packet exiting to the Internal network. An outbound trip would be similar. At any point in the path if the packet is going through what would be considered a filtering process and if fails the filter check the packet is dropped and does not continue any further down the path.

This information is covered in more detail in other in the Troubleshooting chapter of the FortiOS Handbook in the Life of a Packet section.

The incoming packet arrives at the external interface. This process of entering the device is referred to as **ingress**.

Step #1 - Ingress

1. Denial of Service Sensor
2. IP integrity header checking
3. IPsec connection check
4. Destination NAT
5. Routing

Step #2 - Stateful inspection engine

1. Session Helpers
2. Management Traffic
3. SSL VPN
4. User Authentication
5. Traffic Shaping
6. Session Tracking
7. Policy lookup

Step #3 - Security profiles scanning process

1. Flow-based Inspection Engine
2. IPS
3. Application Control
4. Data Leak Prevention
5. Email Filter
6. Web Filter
7. Anti-virus
8. Proxy-based Inspection Engine
9. VoIP Inspection
10. Data Leak Prevention
11. Email Filter
12. Web Filter
13. Anti-virus
14. ICAP

Step #4 - Egress

1. IPsec
2. Source NAT
3. Routing

FortiGate modes

The FortiGate unit has a choice of modes that it can be used in, either NAT/Route mode or Transparent mode. The FortiGate unit is able to operate as a firewall in both modes, but some of its features are limited in Transparent mode. It is always best to choose which mode you are going to be using at the beginning of the set up. Once you start configuring the device, if you want to change the mode you are going to lose all configuration settings in the change process.

NAT/Route mode

NAT/Route mode is the most commonly used mode by a significant margin and is thus the default setting on the device. As the name implies the function of NAT is commonly used in this mode and is easily configured but there is no requirement to use NAT. The FortiGate unit performs network address translation before IP packets are sent to the destination network.

These are some of the characteristics of NAT/Route mode:

- Typically used when the FortiGate unit is a gateway between private and public networks.
- Can act as a router between multiple networks within a network infrastructure.
- When used, the FortiGate unit is visible to the networks that is connected to.
- Each logical interface is on a distinct subnet.
- Each Interface needs to be assigned a valid IP address for the subnet that it is connected to it.

Transparent mode

Transparent mode is so named because the device is effectively transparent in that it does not appear on the network in the way that other network devices show as a nodes in the path of network traffic. Transparent mode is typically used to apply the FortiOS features such as Security Profiles etc. on a private network where the FortiGate unit will be behind an existing firewall or router.

These are some of the characteristics of Transparent mode:

- The FortiGate unit is invisible to the network.
- All of its interfaces are on the same subnet and share the same IP address.
- The FortiGate unit uses a Management IP address for the purposes of Administration.
- Still able to use NAT to a degree, but the configuration is less straightforward

In Transparent mode, you can also perform NAT by creating a security policy or policies that translates the source addresses of packets passing through the FortiGate unit as well as virtual IP addresses and/or IP pools.

Quality of Service

The Quality of Service (QoS) feature allows the management of the level of service and preference given to the various types and sources of traffic going through the firewall so that the traffic that is important to the services and functions connecting through the firewall gets the treatment required to ensure the level of quality that is required. QoS can be helpful for organizations that are trying to manage their voice and streaming multi-media traffic, which can rapidly consume bandwidth. Both voice and streaming multi-media are sensitive to latency. FortiGate units support QoS using traffic policing, traffic shaping, and queuing.

Traffic policing

Packets are dropped that do not conform to bandwidth limitations

Traffic shaping

Assigning minimum levels of bandwidth to be allocated to specific traffic flows to guarantee levels of service or assigning maximum levels of bandwidth to be allocated to specific traffic flows so that they do not impede other flows of traffic.

This helps to ensure that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Traffic shaping also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows that are greater than the maximum rate are subject to traffic policing.

Queuing

Assigning differing levels of priority to different traffic flows so that traffic flows that are adversely effected by latency are prevented from being effected by traffic flows that are not subject to the effects of latency. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

An example of where you would want to use something like this is if you had competing traffic flows of Voice over IP traffic and email traffic. The VoIP traffic is highly susceptible to latency issues. If you have a delay of a few seconds it is quickly noticeable when it is occurring. Email on the other hand can have a time delay of much longer and it is highly unlikely that it will be noticed at all.

By default, the priority given to any traffic is high, so if you want to give one type of traffic priority over all other traffic you will need to lower the priority of all of the other traffic.

Interfaces and zones

A Firewall is a gateway device that may be the nexus point for more than 2 networks. The interface that the traffic is coming in on and should be going out on is a fundamental concern for the purposes of routing as well as security. Routing, policies and addresses are all associated with interfaces. The interface is essentially the connection point of a subnet to the FortiGate unit and once connected can be connected to other subnets.

Physical interfaces or not the only ones that need to be considered. There are also virtual interfaces that can be applied to security policies. VLANs are one such virtual interface. Interfaces if certain VPN tunnels are another.

Policies are the foundation of the traffic control in a firewall and the Interfaces and addressing is the foundation that policies are based upon. Using the identity of the interface that the traffic connects to the FortiGate unit tells the firewall the initial direction of the traffic. The direction of the traffic is one of the determining factors in deciding how the traffic should be dealt with. You can tell that interfaces are a fundamental part of the policies because, by default, this is the criteria that the policies are sorted by.

Zones are a mechanism that was created to help in the administration of the firewalls. If you have a FortiGate unit with a large number of ports and a large number of nodes in you network the chances are high that there is going to be some duplication of policies. Zones provide the option of logically grouping multiple virtual and physical FortiGate firewall interfaces. The zones can then be used to apply security policies to control the incoming and outgoing traffic on those interfaces. This helps to keep the administration of the firewall simple and maintain consistency.

For example you may have several floors of people and each of the port interfaces could go to a separate floor where it connects to a switch controlling a different subnet. The people may be on different subnets but in terms

of security they have the same requirements. If there were 4 floors and 4 interfaces a separate policy would have to be written for each floor to be allowed out on to the Internet off the WAN1 interface. This is not too bad if that is all that is being done, but now start adding the use of more complicated policy scenarios with Security Profiles, then throw in a number of Identity based issues and then add the complication that people in that organization tend to move around in that building between floors with their notebook computers.

Each time a policy is created for each of those floors there is a chance of an inconsistency cropping up. Rather than make up an additional duplicate set of policies for each floor, a zone can be created that combines multiple interfaces. And then a single policy can created that uses that zone as one side of the traffic connection.

Firewall objects

As was mentioned earlier, the components of the FortiGate firewall go together like interlocking building blocks. The Firewall objects are a prime example of those building blocks. They are something that can be configured once and then used over and over again to build what you need. They can assist in making the administration of the FortiGate unit easier and more intuitive as well as easier to change. By configuring these objects with their future use in mind as well as building in accurate descriptions the firewall will become almost self documenting. That way, months later when a situation changes, you can take a look at a policy that needs to change and use a different firewall object to adapt to the new situation rather than build everything new from the ground up to accommodate the change.

This chapter includes information about the following Firewall objects:

- Addresses
- Services and TCP ports
- Firewall schedules
- Security profiles

UUID support

A Universally Unique Identified (UUID) attribute has been added to some firewall objects, so that the logs can record these UUID to be used by a FortiManager or FortiAnalyzer unit. The objects currently include:

- Addresses, both IPv4 and IPv6
- Address Groups, both IPv4 and IPv6
- Virtual IPs, both IPv4 and IPv6
- Virtual IP groups, both IPv4 and IPv6
- Policies, IPv4,IPv6 and IP64

A UUID is a 16-octet (128-bit) number that is represented by 32 lowercase hexidecimal digits. The digits are displayed in five groups separated by hyphens (-). The pattern is 8-4-4-4-12; 36 digits if you include the hyphens.

Note: UUID is only supported on large-partition platforms (>=128M)

Addresses

Firewall addresses define sources and destinations of network traffic and are used when creating policies. When properly set up these firewall objects can be used with great flexibility to make the configuration of firewall policies simpler and more intuitive. The FortiGate unit compares the IP addresses contained in packet headers with a security policy's source and destination addresses to determine if the security policy matches the traffic.

The addresses in the FortiGate unit can include:

- IPv4 addresses
- IPv6 addresses
- IPv4 Address Groups
- IPv6 Address Groups

- IP Pools
- Virtual IP Addresses
- Geography based addresses
- Wildcard addresses and netmasks
- Fully Qualified Domain Name addresses
- Multicast addresses

Interfaces

When setting up an address one of the parameters that is asked for is the interface. This means that the system will expect to see that address only on the interface that you select. You can only select one interface. If you expect that the address may be seen at more than one interface you can choose the “any” interface option. Whenever, possible it is best to choose a more specific interface than the “any” option because in the GUI configuration of firewall policies there is a drop down field that will show the possible addresses that can be used. The drop down will only show those addresses that can be on the interface assigned for that interface in the policy.

Example:

- You have an address called “XYZ”.
- “XYZ” is set to the WAN1 interface because that is the only interface that will be able to access that address.
- When you are selecting a Source Address in the Web-based Manager for a policy that is using the DMZ the address “XYZ” will not be in the drop-down menu.

When there are only 10 or 20 addresses this is not a concern, but if there are a few hundred addresses configured it can make your life easier.

Addresses, address groups, and virtual IPs must have unique names to avoid confusion in firewall policies. If an address is selected in a policy, the address cannot be deleted until it is deselected from the policy.

Addressing Best Practices Tip

The other reason to assign a specific interface to addresses is that it will prevent you from accidentally assigning an address where it will not work properly. Using the example from earlier, if the “XYZ” address was assigned to the “Any” interface instead of WAN1 and you configure the “XYZ” address.

IPv4 addresses

When creating an IPv4 address there are a number of different types of addresses that can be specified. These include:

- Subnet
- IP Range
- FQDN
- Geography
- URL Pattern (Explicit Proxy)

Which one chosen will depend on which method most easily yet accurately describes the addresses that you are trying to include with as few entries as possible based on the information that you have. For instance, if you are trying to discribe the addresses of a specific company’s web server but it you have no idea of how extensive there

webserver farm is you would be more likely to use a Fully Qualified Domain Name (FQDN) rather than a specific IP address. On the other hand some computers don't have FQDNs and a specific IP address must be used.

The following is a more comprehesive description of the differnt types of addresses.

Subnet addresses

The subnet type of address is expressed using a host address and a subnet mask. From a strickly mathematical stand point this is the most flexible of the types because it can refer to as little as the address for one computer or as many as all of them.

It is usally used when refering to your own internal addresses because you know what they are and they are usually administered in groups that are nicely deferentiated along the lines of the old A, B, and C classes of IPv4 addresses. They are also addresses that are not likely to change with the changing of Internet Service Providers (ISP).

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a firewall address can be:

- A single host such as a single computer with the address 192.45.46.45
- A range of hosts such as all of the hosts on the subnet 192.45.46.1 to 192.45.46.255
- All hosts, represented by 0.0.0.0 which matches any IP address

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR formatted netmasks to dotted decimal format. Example formats:

- Netmask for a class A subnet of 16,777,214 usable addresses: 255.0.0.0, or /8
- Netmask for a class B subnet of 65,534 usable addresses: 255.255.0.0, or /16
- Netmask for a class C subnet of 254 usable addresses: 255.255.255.0, or /24
- Netmask for subnetted class C of 126 usable addresses: 255.255.255.128, or /25
- Netmask for subnetted class C of 62 usable addresses: 255.255.255.128, or /26
- Netmask for subnetted class C of 30 usable addresses: 255.255.255.128, or /27
- Netmask for subnetted class C of 14 usable addresses: 255.255.255.128, or /28
- Netmask for subnetted class C of 6 usable addresses: 255.255.255.128, or /29
- Netmask for subnetted class C of 2 usable addresses: 255.255.255.128, or /30
- Netmask for a single computer: 255.255.255.255, or /32
- Netmask used with 0.0.0.0 to include all IP addresses: 0.0.0.0, or /0

So for a single host or subnet the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

Creating a subnet address

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select **Create New**.
   - If you use the down arrow next to **Create New**, select **Address**.

3. Choose the **Category, "Address".**
4. Input a **Name** for the address object.
5. Select the **TypeSubnet** from the dropdown menu.
6. Input the host address and subnet mask in the **Subnet / IP Range** field.
7. Select the **Interface** from the dropdown menu.
8. Check the **Visibility** box.
9. Input any additional information in the **Comments** field.
10. Press **OK.**

Example

Example of a Subnet address for a database server on the DMZ:

Category	Address
Name	DB_server_1
Type	Subnet
Subnet / IP Range	192.168.50.26
Interface	DMZ
Visibility	[checked]
Comments	Database server used by public facing company webservers

IP range addresses

Where the Subnet address is good a representing a standardized group of addresses that are subnets the IP Range type of address can describe a group of addresses while being specific and granular. It does this by specifying a continuous set of IP addresses between one specific IP address and another. While it is most common that this range is with a subnet it is not a requirement. For instance, 192.168.1.0/24 and 192.168.2.0/24 would be 2 separate subnets but if you wanted to descript the top half of one and the bottom half of the other you could describe the range of 192.168.1.128-192.168.2.127. It's also a lot easier that trying to calculate the correct subnet mask.

The format would be:

x.x.x.x-x.x.x.x, such as 192.168.110.100-192.168.110.120

There is a notation that is commonly used and accepted by some devices that follows the format:

x.x.x.[x-x], such as 192.168.110.[100-120]

This format is not recognized in FortiOS 5.2 as a valid IP Range.

Creating a IP range address

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select **Create New**.

- If you use the down arrow next to **Create New**, select **Address**.

3. Choose the **Category, "Address".**
4. Input a **Name** for the address object.
5. Select the **TypeIP Range** from the dropdown menu.
6. Input the host address and subnet mask in the **Subnet / IP Range** field.
7. Select the **Interface** from the dropdown menu.
8. Check the **Visibility** box.
9. Input any additional information in the **Comments** field.
10. Press **OK.**

Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Category	Address
Name	Guest_users
Type	IP Range
Subnet / IP Range	192.168.100.200-192.168.100.240
Interface	Port1
Visibility	[checked]
Comments	Computers on the 1st floor used by guests for Internet access.

IP Range addresses can now be configured for IPv6 addresses. The only differences in creating an IPv6 IP Range address is that you would choose IPv6 Address for the Category and the syntax of the address in the Subnet/IP Range field would be in the format of 2001:0db8:0000:0002:0:0:0:20-2001:0db8:0000:0004:0:0:0:20

FQDN addresses

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of the service to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host_name>.<top_level_domain_name> such as example.com
- <host_name>.<second_level_domain_name>.<top_level_domain_name>, such as mail.example.com

When creating FQDN entries it is important to remember that:

- Wildcards are not supported in FQDN address objects
- While there is a level of convention that would imply it, “www.example.com” is not necessarily the same address of “example.com”. they will each have their own records on the DNS server.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. DNS servers in the past were not seen as potential targets because the thinking was that there was little of value on them and therefore are often not as well protected as some other network resources. People are becoming more aware that the value of the DNS server is that in many ways it controls where users and computers go on the Internet. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select **Create New**.
   - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, “Address”.**
4. Input a **Name** for the address object.
5. Select the **TypeFQDN** from the dropdown menu.
6. Input the domain name in the **FQDN** field.
7. Select the **Interface** from the dropdown menu.
8. Check the **Visibility** box.
9. Input any additional information in the **Comments** field.
10. Press **OK.**

Example

Example of a FQDN address for a remote FTP server used by Accounting team:

Category	Address
Name	Payroll_FTP_server
Type	FQDN
FQDN	ftp.payrollcompany.com
Interface	any
Visibility	[checked]
Comments	Third party FTP server used by Payroll.

Geography based addresses

Geography based addressing enables you to design policies based on addresses that are associated with a country.

This feature can be used to make either inclusive or exclusive policies. For instance, if you have a SSL VPN where the users will only be connecting from a single country, but you don't know from where in that country, you can filter out any connections coming in that are from outside that country.

On the other side of the equation, if you find that you are constantly being attacked by malicious intruders from a few countries that you have no dealings with you can block access to them before any traffic comes through.

The matching of geographical country designations to an IP address is achieved by collecting data from any IP addresses that connect to any of the FortiGuard Servers throughout the world. As a secondary task, when a FortiGuard server connects to an IP it also does a search on the Country of origin for the address and updates the database.

There is no single comprehensive list of IP addresses and their locations available because IP addresses can be transferred between ISPs or countries and some organization may not keep complete or up-to-date records regarding locations. FortiGuard Services are constantly updating their database of addresses matched to locations, but the database is dynamic and there may be addresses that have not been resolved to a location. While this means that there can be gaps in the completeness of the database it is possible to fill them in manually by means local to your FortiGate unit.

FortiOS IPv6 does not support the creation of geography-based address objects. This feature is for IPv4 addresses only.

Best Practices Tip:

Based on the limitation of the IP address matched to country database, it is best to use this type of address in a group with other addresses to fill in the gaps. For instance, if you are a company in Country "A" and all of your employees that will be using the SSL-VPN connection are in that country, the best practice would be to create an address group that includes the geographical address of Country "A". As valid addresses appear that are not allowed, you can add these other IPs to that group using IP addresses or IP range addresses without having to change the policy itself.

If you are trying to block addresses the principle works just the same. Your logs show that someone from IP address x.x.x.x has been trying to connect inappropriately to your network. You use a IP locator web site to determine that they have been attempting to connect from Country “X”. Up until now they have not been successful, but you don’t deal with the country they are connecting from so don’t mind blocking the whole country. Create an address group that is designed for Blocking Access to any addresses in it, then add the geographical address for Country “X”. Even if the policy does not block every single IP address from that country you have greatly increased your odds of blocking potential intrusion attempts. As your logs show other attempts you can look them up in an IP locator web site and if they are from the same country you can add the IP address for the subnet that they are connecting from.

Creating a geography address

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select **Create New**.
   - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, “Address”.**
4. Input a **Name** for the address object.
5. Select the **Type,Geography** from the dropdown menu.
6. Select the country from the dropdown menu in the **Country** field.

   The bottom of the dropdown menu has a search field so that you don’t have to scroll through the entire list of countries.
7. Select the **Interface** from the dropdown menu.
8. Check the **Visibility** box.
9. Input any additional information in the **Comments** field.
10. Press **OK.**

Example

Example of a Geography address for a country that should be able to access resourses on the network.

Category	Address
Name	United States
Type	Geography
Country	United States
Interface	any
Visibility	[checked]
Comments	

Configuring the address in the CLI

Enter the following CLI commands:

```
config firewall address
   edit Cuba
      set type geography
      set country CN
      set interface wan1
   end
```

Overrides

It is possible to assign a specific ip address range to a customized country ID. Generally, geographic addressing is done at the VDOM level; it could be considered global if you are using the root VDOM, but the geoip-override setting is a global setting.

```
config system geoip-override
   edit "test"
      set country-id "A0"
         config ip-range
            edit 1
               set start-ip 7.7.7.7
               set end-ip 7.7.7.8
               next
            edit 2
               set start-ip 7.7.10.1
               set end-ip 7.7.10.255
               end
```

- While the setting exists in the configuration file, the system assigns the country-id option automatically.
- While you can use "edit 1" and "edit 2", it is simpler to use "edit 0" and let the system automatically assign an ID number.

After creating a customized Country by using geoip-override command, the New country name has been added automatically to the country list and will be available on the Firewall Address Country field.

URL pattern addresses

This address is different from the other addresses in that it is not designed to be used in the normal firewall policy configuration. It is intended to be used only with explicit web proxies, and then only as a destination. In some respects it is like a FQDN address in that it uses DNS to look up the IP address that represents but it then goes a little more granular and further filters by the URL that is used to specify a location within the website itself. Wildcard characters can even be used to keep the address from being too granular.

Creating a IP range address

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select **Create New**.
   - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, “Address”.**
4. Input a **Name** for the address object.
5. Select the **Type,URL Pattern (Explicit Proxy)** from the dropdown menu.
6. Enter the URL value.

7. Select the **Interface** from the dropdown menu.
8. Check the **Visibility** box.
9. Input any additional information in the **Comments** field.
10. Press **OK.**

Example

Example of a URL pattern address for a wiki on the example.com website.

Category	Address
Name	Example.com_wiki
Type	URL Pattern (Explicit Proxy)
URL Pattern	example.com/wiki/*
Interface	any
Visibility	[checked]
Comments	<optional>

Address groups

Address groups are designed for ease of use in the administration of the device. If you have a number of addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy refers to them.

The use of groups is not required. If you have a number of different addresses you could add them individually to a policy and the FortiGate firewall will process them just as quickly and efficiently as if they were in a group, but the chances are that if you have used a group once you could need to use it again and depending on the number of addresses involved entering them individually for each policy can become tedious and the likelihood of an address being missed becomes greater. If you have a number of policies using that combination of addresses it is much easier to add or subtract addresses from the group than to try and remember all of the firewall policies that combination of addresses was used in. With the group, you only have to make the one edit and it is used by any firewall policy using that address group.

Because security policies require addresses with homogenous network interfaces, address groups should contain only addresses bound to the same network interface, or to Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

IPv4 address groups and IPv6 address groups are created and treated separately. You cannot mix IPv4 firewall addresses and IPv6 firewall addresses in the same address group. Because the Internet is currently based on IPv4 addresses IPv6 address groups cannot include FQDN or Geography based addresses.

Creating an address group

The method for creating either a IPv4 group or an IPv6 group is idential except for the selection of **Type**.

1. Go to **Policy & Objects > Objects > Addresses.**
2. Select the down arrow next to Create New, select **Address Group**.
3. Choose the **Type,** that is applicable to the proposed sellection of addresses**.**
4. Input a **Group Name** for the address object.
5. Check the **Show in Address List** box.
6. Next to **Members** there is a dropdown menu that can be used to select from the available Address objects. It is possible to select more than 1 entry. Just select the green plus sign next to the field to add an additional entry. Select the “X” icon in the field to remove an entry.
7. Input any additional information in the **Comments** field.
8. Press **OK.**

UUID support

Syntax:

```
config firewall {address|addres6|addgrp|addgrp6}
   edit 1
      set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
      next
   end
```

Virtual IPs

The mapping of a specific IP address to another specific IP address is usually referred to as Destination NAT. FortiOS has a component that is a bit more specialized along this line called a Virtual IP Address, sometimes referred to as a VIP. FortiOS uses a Virtual IP address to map an External IP address to an IP address. This address does not have to be an individual host, it can also be an address range. This mapping can include all TCP/UDP ports or if Port Forwarding is enabled it will only refer to the specific ports configured.

Virtual IP addresses are typically used to NAT external or Public IP addresses to internal or Private IP addresses. Using a Virtual IP address between 2 internal Interfaces made up of Private IP addresses is possible but there is rarely a reason to do so as the 2 networks can just use the IP addresses of the networks without the need for any address translation. Using a Virtual IP address for traffic going from the inside to the Internet is even less likely to be a requirement, but it is supported.

Something that needs to be considered when there are multiple Public IP addresses on the external interface(s) is that when a Virtual IP address is used without Port Forwarding enabled there is a reciprocal effect as far as traffic flow is concerned. Normally, on a firewall policy where NAT is enabled, for outgoing traffic the internal address is translated to the Public address that is assigned to the FortiGate, but if there is a Virtual IP address with no port forwarding enabled, then the Internal IP address in the Mapped field would be translated to the IP address configured as the External Address in the VIP settings.

Best practice: Put any policies with a VIP right at the beginning of the policy list, with nothing before them. VIP traffic is processed first, before the regular rules of order in policies are applied. The sequence of the policies not containing VIPS will not effect those that do contain VIPS, regardless of the order they are in. Put VIP policies before any others to remind yourself of where they really are in the sequence. For more on this topic, read the "Exception to policy order" on page 1009.

Example

- The assigned External address (WAN1) of the FortiGate unit is 172.12.96.3 with a subnet mask of 255.255.255.128
- There is a Virtual IP address set up to map the external address 172.12.96.127 on WAN1 to the internal IP address of 192.168.1.127
- Port Forwarding is not enabled because you want all allowed traffic going to the external IP address to go to this server.

In this case any outbound traffic from 192.168.1.127 will go out on WAN1 with the IP address of 172.12.96.127 as the source IP address.

In terms of actually using the Virtual IP address, they would be using in the security policies in the same places that other addresses would be used, usually as a Destination Address.

UUID support for VIP

UUID is now supported in for virtual IPs and virtual IP groups. This includes virtual IPs for IPv4, IPv6, NAT46, and NAT64. To view the UUID for these objects in a FortiGate unit's logs, log-uuid must be set to extended mode, rather than policy-only (which only shows the policy UUID in a traffic log). UUID can only be configured through the CLI

Syntax:

```
config sys global
   set log-uuid {disable | policy-only | extended}
end
```

There is another type of address that the term “virtual IP address” commonly refers to which is used in load balancing and other similar configurations. In those cases, a number of devices share a separately created virtual IP address that can be sent to multiple possible devices. In FortiOS these are referred to as Virtual Servers and are configured in the “Load Balance” section.

Dynamic VIP according to DNS translation

When a dynamic virtual IP is used in a policy, the dynamic DNS translation table is installed along with the dynamic NAT translation table into the kernel. All matched DNS responses will be translated and recorded regardless if they hit the policy. When a client request hits the policy, dynamic NAT translation will occur if it matches a record, otherwise the traffic will be blocked.

Syntax

```
config firewall vip
   edit "1"
      set type dns-translation
      set extip 192.168.0.1-192.168.0.100
      set extintf "dmz"
      set dns-mapping-ttl 604800
      set mappedip "3.3.3.0/24" "4.0.0.0/24"
      end
   end
```

Creating a virtual IP

1. Go to **Policy & Objects > Objects > Virtual IPs.**
2. Select **Create New**.
   - If you use the down arrow next to Create New, select **Virtual IP**.
3. Choose the **VIP Type.**

   The options available are:

   a. IPv4 VIP - IPv4 on both sides of the FortiGate Unit.

   b. IPv6 VIP - IPv6 on both sides of the FortiGate Unit.

   c. NAT46 VIP - Going from an IPv4 Network to an IPv6 Network.

   d. NAT64 VIP - Going from an IPv6 Network to an IPv4 Network.

   Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface.
4. Input a **Name** for the Virtual IP.
5. Input any additional information in the **Comments** field.
6. Using the dropdown menu for the Interface Field, choose the incoming interface for the traffic.
   The IPv4 VIP Type is the only one that has a field for the interface. This is a legacy function from previous versions so that they can be upgraded without complicated reconfigureation. The External IP address, which is a required field, tells the unit which interface to use so it is perfectly acceptable to choose **Any** as the interface. In some configurations, if the Interface field is not set to **Any** the VIP is not one of the displayed options when choosing a destination address.
7. If only specific IP addresses are allowed to be the source address for traffic uing the VIP, check the box for the **Source Address Filter**.

   a. To specific the allowed address range select **Create New.**

   b. Enter the ip address for the start of the set of IP address(es) in the **Range Start** field.

   c. Enter the ip address for the end of the set of IP address(es) in the **Range End** field.
8. Enter the IP address for the **External IP Address/Range**.
   If there is a single IP address, use that address in both fields.
9. Set the **Mapped IP Type**.
   This will be either Subnet or Address Range.
   If you only have a single destination address you can use either:
   - **Subnet**: x.x.x.x/32
   - **Address Range**: x.x.x.x - x.x.x.x, where x.x.x.x is the same IP address.
10. Enter the IP address(es) for the **Mapped IP Address/Range**.
    This will be the address of the host that the traffic is being directed to.
11. If you are only going to use specific ports, enable **Port Forwarding**.

    a. Select one of 3 **Protocol** types:
    - **TCP**
    - **UDP**
    - **SCTP**

b. Enter the port number or range that the traffic will be connecting to in the **External Service Port** fields.

c. Enter the port number or range that is the final destination of the traffic in the **Map to Port** fields

12. Press **OK.**

Example

This example is for a VIP that is being used to direct traffic from the external IP address to a webserver on the internal network.The webserver is for company use only. The company's public facing webserver already used port 80 and there is only one IP external IP address so the traffic for this server is being listened for on port 8080 of the external interface and being sent to port 80 on the internal host.

VIP Type	IPv4
Name	Internal_Webserver
Comments	Webserver with Colaboration tools for Corporate employees
Interface	Any
Source Address Filter	<list of IP addresses of remote users>
External IP Address/Range	172.13.100.27 <this would normally be a public IP address
Mapped IP Type	Subnet
Mapped IP Address/Range	192.168.34.150
Port Forwarding	enabled
Protocol	TCP
External Service Port	8080 - 8080
Map to Port	80 - 80

Virtual IP groups

Just like other address, Virtual IP addresses can be organized into groups for ease of administration. If you have multiple virtual IPs that are likely to be associated to common firewall policies rather than add them individually to each of the policies you can add the instead. That way, if the members of the group change then any changes made to the group will propagate to all of the policies using that group.

When using a Virtual IP address group the firewall policy will take into account all of the configured parameters of the Virtual IPs: IP addresses, Ports and port types.

Creating a virtual IP group

1. Go to **Policy & Objects > Objects > Virtual IPs.**
2. Use the down arrow next to Create New, select **Virtual IP Group**.
3. Select the **Type** fo VIP group you wish to create.
   The options available are:
   a. **IPv4 VIP** - IPv4 on both sides of the FortiGate Unit.
   b. **IPv6 VIP** - IPv6 on both sides of the FortiGate Unit.
   c. **NAT46 VIP** - Going from an IPv4 Network to an IPv6 Network.
   d. **NAT64 VIP** - Going from an IPv6 Network to an IPv4 Network.
   Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface.The options will be:
4. Enter a **Name** for the VIP
5. Enter any additional information in the **Comments** field.
6. Use the dropdown menu of the **Interface** field to select the interface that the member VIPs are associated with, if any.
7. Use the dropdown menu fo the **Members** field to select the VIPs that will be part of the group.
8. Press **OK.**

IP pools

IP pools are a mechanism that allow sessions leaving the FortiGate Firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses will be used instead of the IP address assigned to that FortiGate interface.

When using IP pools for NATing, there is a limitation that must be taken into account. In order for communication to be successful in both directions, it is normal for the source address in the packet header assigned by the NAT process to be an address that is associated with the interface that the traffic is going through. For example, if traffic is going out an interface with the IP address 172.16.100.1, packets would be NATed so that the source IP address would be 172.16.100.1. This way the returning traffic will be directed to the same interface on the same FortiGate that the traffic left from. Even if the packets are assigned a source address that is associated with another interface on the same FortiGate this can cause issues with asymmetrical routing. It is possible to configure the NATed source IP address to be different than the IP address of the interface but you have to make sure that the routing rules of the surrounding network devices take this unorthodox approach into consideration.

There are 4 types of IP Pools that can be configured on the FortiGate firewall:

- One-to-One - in this case the only internal address used by the external address is the internal address that it is mapped to.
- Overload - this is the default setting. Internal addresses other than the one designated in the policy can use this address for the purposes of NAT.
- Fixed Port Range - rather than a single address to be used, there is a range of addresses that can be used as the NAT address. These addresses are randomly assigned as the connections are made.

- Port Block Allocation - this setting is used to allocate a block of port numbers for IP pool users. Two variables will also have to be set. The block size can be set from 64 to 4096 and as the name implies describes the number of ports in one block of port numbers. The number of blocks per user determines how many of these blocks will be assigned. This number can range from 1 to 128.

Be careful when calculating the values of the variables. The maximum number of ports that are available on an address is 65,536. If you chose the maximum value for both variables you will get a number far in excess of the available port numbers.

4096 x 128 = 524,288

One of the more common examples is when you have an email server behind your FortiGate firewall and the range of IP addresses assigned to you by your ISP is more than one. If an organization is assigned multiple IP addresses it is normally considered a best practice to assign a specific address other than the one used for the Firewall to the mail server. However, when normal NAT is used the address assigned to the firewall is also assigned to any outbound sessions. Anti-spam services match the source IP address of mail traffic that they receive to the MX record on DNS servers as an indicator for spam. If there is a mismatch the mail may not get through so there is a need to make sure that the NATed address assigned matches the MX record.

You can also use the Central NAT table as a way to configure IP pools.

Source IP address and IP pool address matching when using a range

When the source addresses are translated to an IP pool that is a range of addresses, one of the following three cases may occur:

Scenario 1:

The number of source addresses equals that of IP pool addresses

In this case, the FortiGate unit always matches the IP addressed one to one.

If you enable fixed port in such a case, the FortiGate unit preserves the original source port. This may cause conflicts if more than one security policy uses the same IP pool, or the same IP addresses are used in more than one IP pool.

Scenario 2:

The number of source addresses is more than that of IP pool addresses

In this case, the FortiGate unit translates IP addresses using a wrap-around mechanism. If you enable fixed port in such a case, the FortiGate unit preserves the original source port. But conflicts may occur since users may have different sessions using the same TCP 5 tuples.

Scenario 3:

The number of source addresses is fewer than that of IP pool addresses

In this case, some of the IP pool addresses are used and the rest of them are not be used.

ARP replies

If a FortiGate firewall interface IP address overlaps with one or more IP pool address ranges, the interface responds to ARP requests for all of the IP addresses in the overlapping IP pools. For example, consider a FortiGate unit with the following IP addresses for the port1 and port2 interfaces:

- port1 IP address: 1.1.1.1/255.255.255.0 (range is 1.1.1.0-1.1.1.255)
- port2 IP address: 2.2.2.2/255.255.255.0 (range is 2.2.2.0-2.2.2.255)

And the following IP pools:

- IP_pool_1: 1.1.1.10-1.1.1.20
- IP_pool_2: 2.2.2.10-2.2.2.20
- IP_pool_3: 2.2.2.30-2.2.2.40

The port1 interface overlap IP range with IP_pool_1 is:

(1.1.1.0-1.1.1.255) and (1.1.1.10-1.1.1.20) = 1.1.1.10-1.1.1.20

The port2 interface overlap IP range with IP_pool_2 is:

(2.2.2.0-2.2.2.255) & (2.2.2.10-2.2.2.20) = 2.2.2.10-2.2.2.20

The port2 interface overlap IP range with IP_pool_3 is:

(2.2.2.0-2.2.2.255) & (2.2.2.30-2.2.2.40) = 2.2.2.30-2.2.2.40

And the result is:

- The port1 interface answers ARP requests for 1.1.1.10-1.1.1.20
- The port2 interface answers ARP requests for 2.2.2.10-2.2.2.20 and for 2.2.2.30-2.2.2.40

Select Enable NAT in a security policy and then select Dynamic IP Pool. Select an IP pool to translate the source address of packets leaving the FortiGate unit to an address randomly selected from the IP pool. Whether or not the external address of an IP Pool will respond to an ARP request can be disabled. You might want to disable the ability to responded to ARP requests so that these address cannot be used as a way into your network or show up on a port scan.

IP pools and zones

Because IP pools are associated with individual interfaces

IP pools cannot be set up for a zone. IP pools are connected to individual interfaces.

Creating a dynamic IP pool

A dynamic IP pool is essintially one in which the IP address that is assigned to the sending computer is not known until the session is created, therefore at the very least it will have to be a pool of at least 2 potential addresses. A quick example would be an IP pool for users of a VPN.

IP Pool Type	IPv4 Pool
Name	Sales_Group_VPN_Users
Comments	<optional>
Type	One-to-One
External IP Range	10.23.0.50 - 10.23.0.75
ARP Reply	[checked]

Fixed port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

However, enabling the use of a fixed port means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

Match-VIP

The match-vip feature allows the FortiGate unit to log virtual IP traffic that gets implicitly dropped. This feature eliminates the need to create two policies for virtual IPs; one that allows the virtual IP, and the other to get proper log entry for DROP rules.

For example, you have a virtual IP security policy and enabled the match-vip feature; the virtual IP traffic that is not matched by the policy is now caught.

The match-vip feature is available only in the CLI. By default, the feature is disabled.

Services and TCP ports

There are a number of different services and protocols in use on the Internet. The most commonly known is HTTP which is used by web servers to transmit requests and responses for unencrypted web pages. These services are set up to listen for requests on a numbered port. These services and protocols can use any port from 1 to 65,535. To keep things simple for everyone a large number of the more commonly used services started using a standardized list of ports. For instance, though it is not required, by default, most web servers listen for HTTP requests on port 80 and by default, web browsers will send HTTP traffic to port 80. If you wish to use another port such as 8080 you would put “:8080” at the end of the URL to indicate that you want the browser to use 8080 instead of the default port.

Example

Default URL for HTTP traffic when the web server is listening on the standard HTTP port:

http://fortinet.com

URL to the same address when the web server is listening for HTTP traffic on port 8080

http://fortinet.com:8080

Services represent typical traffic types and application packets that pass through the FortiGate unit. Firewall services define one or more protocols and port numbers associated with each service. Security policies use service definitions to match session types. You can organize related services into service groups to simplify your security policy list.

Many well-known traffic types have been predefined on the FortiGate unit. If there is a service that does not appear on the list you can create a service or edit an existing one. You need to know the ports, IP addresses or protocols of that particular service or application uses, to create a service.

Best Practices

While you can edit a predefined service it is best to leave those ones alone and create a new service and name it something similar such as the same service name with a descriptive identifier appended.

Based on the previous example, instead of the name “HTTP” you could name the service “HTTP8080” or use the application that is using that port, “HTTP-Application”.

Categories

In order to make sorting through the services easier there is a field to categorize the services. The services can be sorted into the following groups:

- Uncategorized
- General
- Web Access
- File Access
- Email
- Network Services
- Authentication
- Remote Access
- Tunnelling
- VoIP, Messaging and Other Applications
- Web Proxy

To create a new category, use the downward pointing arrow next to **Create New** in the **Services** window and choose **Category**. All that will be required is a name for the new category. A comments describing the new category is optional.

Protocol types

One of the fundamental aspects of a service is the type of protocol that use used to define it. When a service is defined one of the following categories of protocol needs to be determined:

- TCP/UDP/SCTP
- ICMP
- ICMP6
- IP

Depending on which of these protocol categories is choose another set of specifications will can also be defined.

TCP/UDP/SCTP

This is the most commonly used service protocol category. Once this category has been selected the other available options to choose are an address, either IP or FQDN, and the protocol and port number.

The protocol will be TCP, UDP or SCTP.

ICMP or ICMP6

When ICMP or ICMP6 is chosen the available options are the ICMP Type and its code.

IP

When IP is the chosen protocol type the addition option is the Protocol Number.

TCP

Transmission Control Protocol (TCP) is one of the core or fundamental protocols of the Internet. It is part of the Transport Layer of the OSI Model. It is designed to provide reliable delivery of data from a program on one device on the network or Internet to another program on another device on the network or Internet. TCP achieves its reliability because it is a connection based protocol. TCP is stream-oriented. It transports streams of data reliably and in order.

TCP establishes a prior connection link between the hosts before sending data. This is often referred to as the handshake. Once the link is established the protocol uses checks to verify that the data transmitted. If an error check fails the data is retransmitted. This makes sure that the data is getting to the destination error free and in the correct order so that it can be put back together into a form that is identical to the way they were sent.

TCP is configured more for reliability than for speed and because of this TCP will likely be slower than a connectionless protocol such as UDP. This is why TCP is generally not used for real time applications such as voice communication or online gaming.

Some of the applications that use TCP are:

- World Wide Web (HTTP and HTTPS)
- Email (SMTP, POP3, IMAP4)
- Remote administration (RDP)
- File transfer (FTP)

UDP

User Datagram Protocol (UDP) like TCP is one of the core protocols of the Internet and part of the Transport Layer of the OSI Model. UDP is designed more for speed than reliability and is generally used for different applications than TCP. UDP sends messages, referred to as datagrams across the network or Internet to other hosts without establishing a prior communication link. In other words, there is no handshake.

UDP is an unreliable service as the datagrams can arrive out of order, duplicated or go missing without any mechanism to verify them. UDP works on the assumption that any error checking is done by the application or is not necessary for the function of the application. This way it avoids the overhead that is required to verify the integrity of the data.

This lack of overhead improves the speed of the data transfer and is why UDP is often used by applications that are time sensitive in nature. UDP's stateless nature is also great for applications that answer a large number of small queries from a large number of clients.

Common uses for UDP are:

- Domain Name Resolution (DNS)
- Time (NTP)
- Streaming media (RTSP, RTP and RTCP)
- Telephone of the Internet (VoIP)
- File Transfer (TFTP)
- Logging (SNMP)
- Online games (GTP and OGP)

SCTP

Stream Control Transmission Protocol (SCTP) is part of the Transport Layer of the OSI Model just like TCP and UDP and provides some of the features of both of those protocols. It is message or datagram orientated like UDP but it also ensures reliable sequential transport of data with congestion control like TCP.

SCTP provides the following services:

- Acknowledged error-free non-duplicated transfer of user data
- Data fragmentation to conform to discovered path MTU size
- Sequenced delivery of user messages within multiple streams, with an option for order-of-arrival delivery of individual user messages
- Optional bundling of multiple user messages into a single SCTP packet
- Network-level fault tolerance through supporting of multi-homing at either or both ends of an association
- Congestion avoidance behavior and resistance to flooding and masquerade attacks

SCTP uses multi-streaming to transport its messages which means that there can be several independent streams of messages traveling in parallel between the points of the transmission. The data is sent out in larger chunks of data than is used by TCP just like UDP but the messages include a sequence number within each message in the same way that TCP does so that the data can be reassembled at the other end of the transmission in the correct sequence without the data having to arrive in the correct sequence.

SCTP is effective as the transport protocol for applications that require monitoring and session-loss detection. For such applications, the SCTP path and session failure detection mechanisms actively monitor the connectivity of the session. SCTP differs from TCP in having multi-homing capabilities at either or both ends and several streams within a connection, typically referred to as an association. A TCP stream represents a sequence of bytes; an SCTP stream represents a sequence of messages.

Some common applications of SCTP include supporting transmission of the following protocols over IP networks:

- SCTP is important in 3G and 4G/LTE networks (for example, HomeNodeB = FemtoCells)
- SS7 over IP (for example, for 3G mobile networks)
- SCTP is also defined and used for SIP over SCTP and H.248 over SCTP
- Transport of Public Switched Telephone Network (PSTN) signaling messages over IP networks.

SCTP is a much newer protocol. It was defined by the IETF Signaling Transport (SIGTRAN) working group in 2000. It was introduced by RFC 3286 and more fully define by RFC 4960.

The FortiGate firewall can apply security policies to SCTP sessions in the same way as TCP and UDP sessions. You can create security policies that accept or deny SCTP traffic by setting the service to “ALL”. FortiOS does not include pre-defined SCTP services. To configure security policies for traffic with specific SCTP source or destination ports you must create custom firewall services for SCTP.

FortiGate units route SCTP traffic in the same way as TCP and UDP traffic. You can configure policy routes specifically for routing SCTP traffic by setting the protocol number to 132. SCTP policy routes can route SCTP traffic according to the destination port of the traffic if you add a port range to the policy route.

You can configure a FortiGate unit to perform stateful inspection of different types of SCTP traffic by creating custom SCTP services and defining the port numbers or port ranges used by those services. FortiGate units support SCTP over IPv4. The FortiGate unit performs the following checks on SCTP packets:

- Source and Destination Port and Verification Tag.
- Chunk Type, Chunk Flags and Chunk Length
- Verify that association exists
- Sequence of Chunk Types (INIT, INIT ACK, etc)
- Timer checking
- Four way handshake checking
- Heartbeat mechanism
- Protection against INIT/ACK flood DoS attacks, and long-INIT flooding
- Protection against association hijacking

FortiOS also supports SCTP sessions over IPsec VPN tunnels, as well as full traffic and event logging for SCTP sessions.

Specific addresses in TCP/UDP/SCTP

In the TCP/UDP/SCTP services it is also possible to set the parameter for a specific IP or Fully Qualified Domain Name address. The IP/FQDN field refers to the destination address of the traffic, not the source. This means for example, that you can set up a custom service that will describe in a policy the TCP traffic over port 80 going to the web site example.com, but you cannot set up a service that describes the TCP traffic over port 80 that is coming from the computer with the address 192.168.29.59.

Protocol port values

The source and destination ports for TCP/UDP/SCTP services are important to get correct. If they are reversed the service will not work. The destination port(s) are the on ones that refer to the ports that the computer will be listening on. These are the port numbers that most people are familiar with when they associate a port number to a protocol. In most cases the source port will be one that is randomly assigned by the computer that is not being already used by another service.

Most people associate HTTP with port 80. This means that a web-server will be listening on port 80 for any http requests being sent to the computer. The computer that is sending the request can use any port that is not already assigned to another service or communication session. There are 65,535 ports that it can randomly assign, but because the ports from 1 to 1024 are normally used for listening for incoming communications it is usually not in that range. It is unless there is a specific instance when you know that a communication will be coming from a predefined source port it is best practice to set the source port range from 1 to 65,535.

ICMP

The Internet Control Message Protocol (ICMP) is a protocol layered onto the Internet Protocol Suite to provide error reporting flow control and first-hop gateway redirection. It is normally used by the operating systems of networked computers to send connectivity status query, response and error messages. It is assigned protocol number 1. There is a version of the protocol for both IPv4 and for IPv6. It is not designed to be absolutely reliable like TCP.

ICMP is not typically used for transporting data or for end-user network applications with the exception of some diagnostic utilities such as ping and traceroute.

ICMP messages are sent in several situations, for example:

- when a datagram cannot reach its destination,
- time exceeded messages
- redirect messages
- when the gateway does not have the buffering capacity to forward a datagram
- when the gateway can direct the host to send traffic on a shorter route.

Some of the specific ICMP message types are:

- ICMP_ECHO
- ICMP_TIMESTAMP
- ICMP_INFO_REQUEST
- ICMP_ADDRESS

For ICMP error messages, only those reporting an error for an existing session can pass through the firewall. The security policy will allow traffic to be routed, forwarded or denied. If allowed, the ICMP packets will start a new session. Only ICMP error messages of a corresponding security policy is available will be sent back to the source. Otherwise, the packet is dropped. That is, only ICMP packets for a corresponding security policy can traverse the FortiGate unit.

ICMP types and codes

ICMP has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

ICMP types and codes

Type Number	Type Name	Optional Code(s)
0	Echo Reply	
1	Unassigned	
2	Unassigned	
3	Destination Unreachable	0 Net Unreachable 1 Host Unreachable 2 Protocol Unreachable 3 Port Unreachable 4 Fragmentation Needed and Don't Fragment was Set 5 Source Route Failed 6 Destination Network Unknown 7 Destination Host Unknown 8 Source Host Isolated 9 Communication with Destination Network is Administratively Prohibited 10 Communication with Destination Host is Administratively Prohibited 11 Destination Network Unreachable for Type of Service 12 Destination Host Unreachable for Type of Service 13 Communication Administratively Prohibited 14 Host Precedence Violation 15 Precedence cutoff in effect
4	Source Quench	
5	Redirect	0 Redirect Datagram for the Network (or subnet) 1 Redirect Datagram for the Host 2 Redirect Datagram for the Type of Service and Network 3 Redirect Datagram for the Type of Service and Host

Type Number	Type Name	Optional Code(s)
6	Alternate Host Address	
7	Unassigned	
8	Echo	
9	Router Advert-isement	
10	Router Selection	
11	Time Exceeded	0 Time to Live exceeded in Transit 1 Fragment Reassembly Time Exceeded
12	Parameter Problem	0 Pointer indicates the error 1 Missing a Required Option 2 Bad Length
13	Timestamp	
14	Timestand Reply	
15	Information Request	
16	Information Reply	
17	Address Mask Request	
18	Address Mask Reply	
19	Reserved (for Security)	
20 - 29	Reserved (for Robustness Exper-iment)	
30	Traceroute	
31	Datagram Con-version Error	

Type Number	Type Name	Optional Code(s)
32	Mobile Host Redirect	
33	IPv6 Where-Are-You	
34	IPv6 I-Am-Here	
35	Mobile Registration	
36	Mobile Registration Reply	
37	Domain Name Request	
38	Domain Name Reply	
39	SKIP	
40	Photuris	
41 - 255	Reserved	

log-invalid-packet

The `log-invalid-packet` CLI setting is one that is intended to log invalid ICMP packets. The exact definition being:

> If the ForitGate unit receives an ICMP error packet that contains an embedded `IP(A,B)|TCP (C,D)` header, then if FortiOS can loacate the A:C -> B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped.

When this field is enabled, the FortiGate also log messages that are not ICMP error packets.

Types of logs covered by `log-invalid-packet`

- Invalid ICMP
  - If ICMP error message verification (see "check-reset-range") is enabled
- Invalid DNS packets
  - DNS packets that contain requests for non-existing domains
- `iprope` check failed
- reverse path check fail
- denied and broadcast traffic
- no session matched

Some other examples of messages that are not errors that will be logged, based on RFC792:

Type 3 messages correspond to "Destination Unreachable Message"

- Type 3, Code 1 = host unreachable
- Type 3, Code 3 = port unreachable

Type 11 messages correspond to "Time Exceeded Message"

- Type 11, Code 0 = time to live exceeded in transit

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in RFC 4443.

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.

ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).

ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

1. Destination Unreachable
2. Time Exceeded
3. Packet Too Big
4. Parameter Problems

Information messages are divided into three groups:

1. Diagnostic messages
2. Neighbor Discovery messages
3. Messages for the management of multicast groups.

ICMPv6 types and codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if

there are any.

Type codes 0 − 127 are error messages and type codes 128 − 255 are for information messages.

ICMPv6 Types and Codes

Type Number	Type Name	Code
0	Reserved	0 - no route to destination 1 - communication with destination administratively prohibited 2 - beyond scope of source address 3 - address unreachable 4 - port unreachable 5 - source address failed ingress/egress policy 6 - reject route to destination 7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit 1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered 1 - unrecognized Next Header type encountered 2 - unrecognized IPv6 option encountered
100	Private Exper-imentation	
101	Private Exper-imentation	
102 - 126	Unassigned	
127	Reserved for expan-sion if ICMPv6 error messages	
128	Echo Request	
129	Echo Replay	

Type Number	Type Name	Code
130	Multicast Listener Query	
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advert-isement	
135	Neighbor Soli-citation	
136	Neighbor Advert-isement	
137	Redirect Message	
138	Router Renum-bering	0 - Router Renumbering Command 1 - Router Renumbering Result 255 - Sequence Number Reset
139	ICMP Node Inform-ation Query	0 - The Data field contains an IPv6 address which is the Subject of this Query. 1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP. 2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.

Type Number	Type Name	Code
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	

Type Number	Type Name	Code
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

IP

Internet Protocol (IP) is the primary part of the Network Layer of the OSI Model that is responsible for routing traffic across network boundaries. It is the protocol that is responsible for addressing. IPv4 is probable the version that most people are familiar with and it has been around since 1974. IPv6 is its current successor and due to a shortage of available IPv4 addresses compared to the explosive increase in the number of devices that use IP addresses, IPv6 is rapidly increasing in use.

When IP is chosen as the protocol type the available option to further specify the protocol is the protocol number. This is used to narrow down which protocol within the Internet Protocol Suite and provide a more granular control.

Protocol number

IP is responsible for more than the address that it is most commonly associated with and there are a number of associated protocols that make up the Network Layer. While there are not 256 of them, the field that identifies them is a numeric value between 0 and 256.

In the Internet Protocol version 4 (IPv4) [RFC791] there is a field called “Protocol” to identify the next level protocol. This is an 8 bit field. In Internet Protocol version 6 (IPv6) [RFC2460], this field is called the “Next Header” field.

Protocol Numbers

#	Protocol	Protocol's Full Name
0	HOPOPT	IPv6 Hop-by-Hop Option
1	ICMP	Internet Control Message Protocol
2	IGMP	Internet Group Management
3	GGP	Gateway-to-Gateway
4	IPv4	IPv4 encapsulation Protocol
5	ST	Stream
6	TCP	Transmission Control Protocol
7	CBT	CBT
8	EGP	Exterior Gateway Protocol
9	IGP	Any private interior gateway (used by Cisco for their IGRP)
10	BBN-RCC-MON	BBN RCC Monitoring
11	NVP-II	Network Voice Protocol
12	PUP	PUP
13	ARGUS	ARGUS
14	EMCON	EMCON
15	XNET	Cross Net Debugger
16	CHAOS	Chaos
17	UDP	User Datagram Protocol
18	MUX	Multiplexing
19	DCN-MEAS	DCN Measurement Subsystems
20	HMP	Host Monitoring
21	PRM	Packet Radio Measurement
22	XNS-IDP	XEROX NS IDP
23	TRUNK-1	Trunk-1

#	Protocol	Protocol's Full Name
24	TRUNK-2	Trunk-2
25	LEAF-1	Leaf-1
26	LEAF-2	Leaf-2
27	RDP	Reliable Data Protocol
28	IRTP	Internet Reliable Transaction
29	ISO-TP4	ISO Transport Protocol Class 4
30	NETBLT	Bulk Data Transfer Protocol
31	MFE-NSP	MFE Network Services Protocol
32	MERIT-INP	MERIT Internodal Protocol
33	DCCP	Datagram Congestion Control Protocol
34	3PC	Third Party Connect Protocol
35	IDPR	Inter-Domain Policy Routing Protocol
36	XTP	XTP
37	DDP	Datagram Delivery Protocol
38	IDPR-CMTP	IDPR Control Message Transport Proto
39	TP++	TP++ Transport Protocol
40	IL	IL Transport Protocol
41	IPv6	IPv6 encapsulation
42	IPv6	SDRPSource Demand Routing Protocol
43	IPv6-Route	Routing Header for IPv6
44	IPv6-Frag	Fragment Header for IPv6
45	IDRP	Inter-Domain Routing Protocol
46	RSVP	Reservation Protocol
47	GRE	General Routing Encapsulation

#	Protocol	Protocol's Full Name
48	DSR	Dynamic Source Routing Protocol
49	BNA	BNA
50	ESP	Encap Security Payload
51	AH	Authentication Header
52	I-NLSP	Integrated Net Layer Security TUBA
53	SWIPE	IP with Encryption
54	NARP	NBMA Address Resolution Protocol
55	MOBILE	IP Mobility
56	TLSP	Transport Layer Security Protocol using Kryptonet key management
57	SKIP	SKIP
58	IPv6-ICMP	ICMP for IPv6
59	IPv6-NoNxt	No Next Header for IPv6
60	IPv6-Opts	Destination Options for IPv6
61		any host internal protocol
62	CFTP	CFTP
63		any local network
64	SAT-EXPAK	SATNET and Backroom EXPAK
65	KRYPTOLAN	Kryptolan
66	RVD	MIT Remote Virtual Disk Protocol
67	IPPC	Internet Pluribus Packet Core
68		any distributed file system
69	SAT-MON	SATNET Monitoring
70	VISA	VISA Protocol
71	IPCV	Internet Packet Core Utility

#	Protocol	Protocol's Full Name
72	CPNX	Computer Protocol Network Executive
73	CPHB	Computer Protocol Heart Beat
74	WSN	Wang Span Network
75	PVP	Packet Video Protocol
76	BR-SAT-MON	Backroom SATNET Monitoring
77	SUN-ND	SUN ND PROTOCOL-Temporary
78	WB-MON	WIDEBAND Monitoring
79	WB-EXPAK	WIDEBAND EXPAK
80	ISO-IP	ISO Internet Protocol
81	VMTP	VMTP
82	SECURE-VMTP	SECURE-VMTP
83	VINES	VINES
84	TTP	TTP
84	IPTM	Protocol Internet Protocol Traffic
85	NSFNET-IGP	NSFNET-IGP
86	DGP	Dissimilar Gateway Protocol
87	TCF	TCF
88	EIGRP	EIGRP
89	OSPFIGP	OSPFIGP
90	Sprite-RPC	Sprite RPC Protocol
91	LARP	Locus Address Resolution Protocol
92	MTP	Multicast Transport Protocol
93	AX.25	AX.25 Frames
94	IPIP	IP-within-IP Encapsulation Protocol

#	Protocol	Protocol's Full Name
95	MICP	Mobile Internetworking Control Pro.
96	SCC-SP	Semaphore Communications Sec. Pro.
97	ETHERIP	Ethernet-within-IP Encapsulation
98	ENCAP	Encapsulation Header
99		any private encryption scheme
100	GMTP	GMTP
101	IFMP	Ipsilon Flow Management Protocol
102	PNNI	PNNI over IP
103	PIM	Protocol Independent Multicast
104	ARIS	ARIS
105	SCPS	SCPS
106	QNX	QNX
107	A/N	Active Networks
108	IPComp	IP Payload Compression Protocol
109	SNP	Sitara Networks Protocol
110	Compaq-Peer	Compaq Peer Protocol
111	IPX-in-IP	IPX in IP
112	VRRP	Virtual Router Redundancy Protocol
113	PGM	PGM Reliable Transport Protocol
114		any 0-hop protocol
115	L2TP	Layer Two Tunneling Protocol
116	DDX	D-II Data Exchange (DDX)
117	IATP	Interactive Agent Transfer Protocol
118	STP	Schedule Transfer Protocol

#	Protocol	Protocol's Full Name
119	SRP	SpectraLink Radio Protocol
120	UTI	UTI
121	SMP	Simple Message Protocol
122	SM	SM
123	PTP	Performance Transparency Protocol
124	ISIS over IPv4	
125	FIRE	
126	CRTP	Combat Radio Transport Protocol
127	CRUDP	Combat Radio User Datagram
128	SSCOPMCE	
129	IPLT	
130	SPS	Secure Packet Shield
131	PIPE	Private IP Encapsulation within IP
132	SCTP	Stream Control Transmission Protocol
133	FC	Fibre Channel
134	RSVP-E2E-IGNORE	
135	Mobility Header	
136	UDPLite	
137	MPLS-in-IP	
138	manet	
139	HIP	
140	Shim6	
141	WESP	
142	ROHC	

#	Protocol	Protocol's Full Name
143 – 252	Unassigned	Unassigned
253		Use for experimentation and testing
254		Use for experimentation and testing
255	Reserved	

Further information can be found by researching RFC 5237.

Service groups

Just like some of the other firewall components, services can also be bundled into groups for ease of administration.

Creating a service group

1. Go to **Policy & Objects > Objects > Services**.
2. Select the down arrow next to **Create New**, select **Service Group**.
3. Input a Group Name for the list of services.
4. Input any additional information in the Comments field.
5. Choose a **Type**; either **Firewall** or **Explicit Proxy**.
6. Next to Members there is a dropdown menu that can be used to select from the available Services. It is possible to select more than 1 entry. Just select the green plus sign next to the field to add an additional entry. Select the “X” icon in the field to remove an entry.
7. Press **OK**.

Example scenario: Supporting audio/visual conferencing

The feature, and the transmitting of data for the purpose of, Tele-conferencing or Audio/Visual Conferencing is covered by a number of standards:

- The IETF standard known as the Binary Floor Control Protocol (BFCP).
- RFC 4582, for SIP-based video devices
- The ITU standard H.239 (for H.323-based video devices)

While these standards have been set up by various authoritative bodies and can take place on different layers of the OSI model, they share common requirements that are addressed by the FortiGate firewall’s ability to manage the traffic and the protocols involved. This means that the same ability that make the device RFC 4582 compliant makes it compliant with H.239 as well.

To demonstrate how services and service groups are used we show the setup of a firewall that will need to support the connectivity of a video conferencing unit. The FortiGate does not manipulate or change the content of the traffic but it does allow for the traffic to pass through the device. In this case it allow for only the needed

traffic to pass through the device so as to allow the functionality of Audio Visual Conference call but not to allow other traffic through.

The theoretical location for this scenario is a hospital that hosts conferences and lectures from doctors from all over the world, sometimes from multiple locations, using video conferencing technology such as a Polycom Video Conference system. There is a special room set up with dedicated Ethernet connectivity to the Internet. A hospital has a lot of sensitive information going over its network so the setup has to be secure to prevent any chance of penetration.

The approach is fairly simple. The conference room has a dedicated port on the FortiGate (port #7) and its own LAN. We will assume that the interface has already been configured properly. Video conference traffic can come from the Internet to the Polycom in that room and traffic can get out to the Internet, but traffic going to other areas of the hospital network have to go through the FortiGate and traffic going from the Video Conference LAN is thoroughly filtered.

To give an idea of how extensive this can be, we will use an extreme case and include just about all of the services that could be commonly used in one of these setups. The protocols listed here may differ from other setups. It will depend on which features are being used and which equipment is within the network. Always check the documentation that comes with the set up before opening ports into your network.

VIP

In this particular case there is an IP address set aside for the conferencing system so a separate VIP is not needed for every port. One Virtual IP will be created for the system and then only the approved of protocols will be allows through the firewall.

Name	Vid-Conf_Room216
External Interface	wan1
External IP Address/Range	256.87.212.51 – 256.87.212.51
Mapped IP Address/Range	192.168.7.25 – 192.168.7.25
Port Forwarding	not selected

Creating an address for the subnet

In the same way that the VIP was created to identify and direct incoming traffic an address should be created to identify the addresses of computer that will be in the Conference room. This included computers on the LAN as well as the Teleconferencing equipment.

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**.
3. Fill out the fields with the following information:

Category	Address

Name	Port7_subnet
Type	Subnet
Subnet/IP Range	192.168.7.0/255.255.255.0
Interface	port7
Show in address list	checked

Configuring the services

Services already created:

The following are standard services that have already been created by default:

HTTP	TCP 80
SNMP	TCP 161-162/UDP 161-162
LDAP	TCP 389
HTTPS	TCP 443
SYSLOG	UDP 514

Existing services to be edited:

There are a few services that have already been created for you, but they need to be expanded to accommodate the list of protocols listed for this scenario.

The default h323 contains:

- TCP 1503
- UDP 1719
- TCP 1720

We need to add:

- TCP1719

The default SIP contains:

- UDP 5060

We need to add:

- TCP 5060

H323 service

1. Go to **Policy & Objects > Objects > Services**.
2. Scroll down to the section: **VoIP, Messaging & Other Applications**.
3. Select **H323**.
4. Select **Edit**.
5. In the Protocol section add the additional protocol:

Protocol Type	TCP
Destination port /Low	1719

6. Select **OK** to save.

SIP service

1. Go to **Policy & Objects > Objects > Services**.
2. Scroll down to the section: **VoIP, Messaging & Other Applications**.
3. Select **SIP**.
4. Select **Edit**.
5. In the Protocol section add the additional protocol:

Protocol Type	TCP
Destination port /Low	5060

6. Select **OK** to save.

Custom services that need to be created

There are a number of possible services that may need to be added from scratch rather than editing existing ones. While it is possible to create a single custom service that contains all of the open ports needed, it make more sense to make this modular in case only a small subset of the service needs to be added to another policy.

Polycom API

1. Go to **Policy & Objects > Objects > Services**.
2. Select **Create New**.
3. Fill in the fields of the new service with the following information:

Name	Polycom API
Service Type	Firewall
Category	VoIP, Messaging & Other
Protocol Type	TCP/UDP/SCTP

Protocol	TCP/UDP/SCTP
Protocol	TCP
Destination Port - Low:	24
Destination Port - High:	<leave blank>

4. Select **OK**.

Polycom endpoints

1. Go to **Policy & Objects > Objects > Services**.
2. Select **Create New**.
3. Fill in the fields of the new service with the following information:

Name	Polycom Endpoints
Service Type	Firewall
Category	VoIP, Messaging & Other
Protocol Type	TCP/UDP/SCTP
Protocol	TCP
Destination - Low:	3230
Destination - High:	3253

4. Select **OK**.

Other Services to add in the same way:

Name of Service	Category	Protocol & Port #
LDAP secure communications	Authentication	TCP 636
Win 2000 ILS Registration	Network Services	TCP 1002
Gatekeeper discovery	VoIP, Messaging & Other Applications	TCP 1718
Audio Call Control	VoIP, Messaging & Other Applications	TCP 1731
Polycom proprietary Global directory data	VoIP, Messaging & Other Applications	TCP 3601
Polycom People+Content	VoIP, Messaging & Other Applications	TCP 5001
HTTP Server Push	Web Access	

Creating the service group

1. Go to **Firewall Objects > Service > Groups**.
2. Select **Create New**.
3. Build the Service group by filing in the fields with the following information

Group Name	A-V_Conference
Type	Firewall
Members (click in the drop down menu to add the following services)	• HTTP • SNMP • LDAP • HTTPS • SYSLOG • Polycom API • Polycom Endpoints • LDAP secure communications • Win 2000 ILS Registration • Gatekeeper discovery • Audio Call Control • Polycom proprietary Global directory data • Polycom People+Content • HTTP Server Push

Creating the IPS security profile

This is by no means the only way to set up this IPS filter, but it is the way that the fictional System Administrator wants it set up. Yours may be different.

1. Go to Security **Profiles > Intrusion Protection > IPS Sensors**.
2. Create a new sensor.

Name	A-V_Conference-incoming

3. Select **OK.**
4. In the newly created sensor, create a new IPS filter.

Sensor Type	Filter Based
Filter Options	Advanced
Severity	• Critical • High • Medium • Low
Target	Server
OS	Windows

Application	• IIS • other
Protocol **Use the [Show more...] option**	• HTTP • LDAP • SIP • SSL • H323
Packet logging	enabled

Based on these filters there should be somewhere in the neighborhood of 750 signatures that the FortiGate will run traffic against in the IPS engine.

Policies

Incoming policy

A policy has to be made to allow the traffic to come in from the Internet to connect to the Tele-conferencing server equipment.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Fill out the fields with the following information:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wan1
Source Address	all
Outgoing Interface	port7
Destination Address	Vid-Conf_Room216
Schedule	always
Service	A-V_Conference
Action	ACCEPT
Enable NAT	<not enabled>
Logging Options	Logging is a good idea but how much will depend on storage capabilities.
Security Profiles	Turn on IPS and choose “A-V_Conference-incoming”
Traffic Shaping, Web cache, WAN Optimization, Disclaimer:	The use of these features will depend on your network environment and should be decided by the network architect, as the decision will largely be based on network bandwidth, usage and importance of Video conferencing compared to other traffic.

4. Select **OK**.

The policy will then need to be put in the correct position in the sequence of the policies. Because it is a rather focused policy it should be acceptable to place it near the top of the policy order sequence.

Outgoing policy

A policy has to be made to allow the traffic to leave from the subnet in the conference room to the Internet, not only for the traffic for the Tele-conferencing equipment but for normal traffic of users on the Internet such as web research and email. The traffic is outgoing so there is less of a need for an Intrusion Protection System filter, but check with the network architect in case there is a need for using one of the other security profiles.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Fill out the fields with the following information:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port7
Source Address	Port7_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	any
Action	ACCEPT
Enable NAT	enabled Use Destination Interface Address
Logging Options	Logging is a good idea but how much will depend on storage capabilities.
Security Profiles	<see above>
Traffic Shaping, Web cache, WAN Optimization, Disclaimer:	The use of these features will depend on your network environment and should be decided by the network architect, as the decision will largely be based on network bandwidth, usage and importance of Video conferencing compared to other traffic.

4. Select **OK**.

The policy will then need to be put in the correct position in the sequence of the policies.

Firewall schedules

Firewall schedules control when policies are in effect. When you add a security policy on a FortiGate unit you need to set a schedule to determine the time frame in which that the policy will be functioning. While it is not set by default, the normal schedule would be always. This would mean that the policy that has been created is

always function and always policing the traffic going through the FortiGate. The time component of the schedule is based on a 24 hour clock notation or military time as some people would say.

There are two types of schedules: One-time schedules and recurring schedules.

One-Time schedules are in effect only once for the period of time specified in the schedule. This can be useful for testing to limit how long a policy will be in effect in case it is not removed, or it can be used for isolated events such as a conference where you will only need a temporary infrastructure change for a few days.

The time frame for a One-time schedule is configured by using a start time which includes, Year | Month | Day | Hour | Minute and a Stop time which includes the same variables. So while the frequency of the schedule is only once it can last anywhere from 1 minute to multiple years.

Recurring schedules are in effect repeatedly at specified times of specified days of the week. The Recurring schedule is based on a repeating cycle of the days of the week as opposed to every x days or days of the month. This means that you can configure the schedule to be in effect on Tuesday, Thursday, and Saturday but not every 2 days or on odd numbered days of the month.

If a recurring schedule has a stop time that is earlier than the start time, the schedule will take effect at the start time but end at the stop time on the next day. You can use this technique to create recurring schedules that run from one day to the next.

> Because recurring schedules do not work with DENY policies, the strategy when designing a schedule should *not* be to determine when users cannot access a policy but to build the schedules around when it *is* possible to access the policy.

Example

You want to schedule the use of Skype to only between noon (12:00) and 1 p.m. (13:00).

You could create a schedule that allows Skype traffic:

- Starting at Hour:12 and Minute: 00
- Stopping at Hour:13 and Minute: 00
- Set for days of the week: Sunday | Monday |Tuesday |Wednesday | Thursday | Friday | Saturday

Or you could have a schedule that blocks Skype traffic:

- Starting at Hour:13 and Minute: 00 (and goes to the next day)
- Stopping at Hour:12 and Minute: 00
- Set for days of the week: Sunday | Monday |Tuesday |Wednesday | Thursday | Friday | Saturday

Either way is effective for the task but other factors may make one method work better than another in certain situations of it could be just a preference in approach.

Schedule expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this option is set to disable.

A few further settings are needed to make this work.

```
config firewall policy
   edit ID
      set firewall-session-dirty check-new
      end

config system settings
   set firewall-session-dirty check-policy-option
      end
```

Firewall-session-dirty setting

The firewall-session-dirty setting has three options

`check-all`	CPU flushes all current sessions and re-evaluates them. [default]
`check-new`	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
`check-policy-option`	Use the option selected in the firewall-session-dirty field of the firewall policy (check-all or check-new, as above, but per policy).

Schedule groups

You can organize multiple firewall schedules into a schedule group to simplify your security policy list. The schedule parameter in the policy configuration does not allow for the entering of multiple schedules into a single policy so if you have a combination of time frames that you want to schedule the policy for then the best approach, rather than making multiple policies is to use a schedule group.

Example

Your Internet policy allows employees to visit Social Media sites from company computers but not during what is considered working hours. The offices are open a few hours before working hours and the doors are not locked until a few hours after official closing so work hours are from 9 to 5 with a lunch break from Noon to 1:00 p.m.

Your approach is to block the traffic between 9 and noon and between 1:00 p.m. and 5:00 p.m. This means you will need two schedules for a single policy and the schedule group handles this for you. Schedule groups can contain both recurring and one-time schedules. Schedule groups cannot contain other schedule groups.

Schedule expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as

the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this is set to `disable`.

Security policies

One of the foundations upon which a firewall works is the use of policies. These are what bring the other firewall objects and components together into an elegant mechanism for the governing of the traffic going through the network.

This Chapter includes information on the following topics:

- Firewall policies
- Security profiles
- SSL/SSH Inspection
- Identity Based Policies
- Device Identity Policies
- VPN Policies
- Interface Policies
- One-Arm IDS
- Local-In Policies
- Security Policy 0
- Deny Policies
- Accept Policies
- IPv6 Policies
- Fixed Port
- Endpoint Security
- Traffic Logging
- Quality of Service
- Policy Monitor

Firewall policies

The firewall policy is the axis around which most of the other features of the FortiGate firewall revolve. A large portion of the settings in the firewall at some point will end up relating to or being associated with the firewall policies and the traffic that they govern. Any traffic going through a FortiGate unit has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it's processed, if it's processed and even whether or not it's allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the packet's source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it will need to use and the time of day. Using this information the FortiGate firewall attempts to locate a security policy that matches the packet. If it finds a policy that matches the parameters it then looks at the action for that policy. If it is ACCEPT the traffic is allowed to proceed to the next step. If the Action is DENY or a match cannot be found the traffic is not allowed to proceed.

The 2 basic actions at the initial connection are either ACCEPT or DENY:

- If the Action is ACCEPT, the policy action permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy. While you may not see it in the configuration there is the implied subset of the ACCEPT Action that include VPN policies, whether they be an IPsec VPN or SSL.
- If the Action is DENY, the policy action blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A DENY security policy is needed when it is required to log the denied traffic, also called “violation traffic”.

The policy may contain a number of instructions for the FortiGate firewall in addition to the ACCEPT or DENY actions, some of which are optional. Instructions on how to process the traffic can also include such things as:

- Logging Traffic
- Authentication
- Network Address Translation or Port Address Translation
- Use Virtual IPs or IP Pools
- Caching
- Whether to use address or Identity based rules
- Whether to treat as regular traffic or VPN traffic
- What certificates to use
- Security profiles to apply
- Proxy Options
- Traffic Shaping

Firewall policy parameters

As mentioned before, for traffic to flow through the FortiGate firewall there must be a policy that matches its parameters:

Incoming interface

This is the interface or interfaces that the traffic is first connection to the FortiGate unit by. The exception being traffic that the FortiGate generates itself. This is not limited to the physical Ethernet ports found on the device. The incoming interface can also be a logical or virtual interface such as a VPN tunnel, a Virtual WAN link or a wireless interface.

Outgoing interface

After the firewall has processed the traffic it needs to leave a port to get to its destination and this will be the interface or interfaces that the traffic leaves by. This interface, like the **Incoming Interface** is not limited to only physical interfaces.

Source address

The addresses that a policy can receive traffic from can be wide open or tightly controlled. For a public webserver that the world at large should be able to access, the best choice will be “all”. If the destination is a private webserver that only the branch offices of a company should be able to access or a list of internal computers that are the only ones allowed to access an external resource then a group of preconfigured addresses is the better strategy.

Additional parameters under the Source Address, though they are not manditory are:

- **Source User(s)**
  This parameter is based on a user identity that can be from a number of authentication authorities. It will be an account or group that has been set up in advance that can be sellected from the dropdown menu. The exception to this is the feature that allows the importing of LDAP Users. When the feature is used, a small wizard window will appear to guide the user through the setup. The caveat is that the LDAP server object in the **User and Device > Authentication > LDAP Servers** section has to be already configured to allow the use of this import feature.
- **Source Device Type**
  This parameter is for narrowing down the traffic sending devices to those that the FortiGate is familiar with. Again the the contents of this parameter need to be a preconfigured object and these are defined at **User and Device > Device > Device Definitions.** This parameter can limit the devices that can connect to this policy to those specific MAC addresses that are already known by the FortiGate and are approved for the policy.

Destination address

In the same way that the source address may need to be limited, the destination address can be used as a traffic filter. When the traffic is destined for internal resources the specific address of the resourece can be defined to better protect the other resources on the network. One of the specialized destination address options is to use a Virtual IP address. The destination address doesn't need to be interal you can define policies that are only for connecting to specific addresses on the Internet.

Schedule

The time frame that is applied to the policy. This can be something as simple as a time range that the sessions are allowed to start such as between 8:00 am and 5:00 pm. Something more complex like business hours that include a break for lunch and time of the session's initiation may need a schedule group because it will require multiple time ranges to make up the schedule.

Service

The service or service chosen here respresent the TCP/IP suite port numbers that will most commonly be used to transport the named protocols or group of protocols. This will be a little different than Application Control which looks more closely at the packets to determine the actual protocol used to create them.

Without all six (possibly 8) of these things matching, the traffic will be declined. Each traffic flow requires a policy and the direction is important as well. Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy there is often reference to the traffic flow, but most communication is a two way connection so trying to determine the direction of the flow can be somewhat confusing. If traffic is HTTP web traffic the user sends a request to the web site, but most of the traffic flow will be coming from the web site to the user. Is the traffic flow considered to be from the user to the web site, the web site to the user or in both directions? For the purposes of determining the direction for a policy the important factor is the direction of the initiating communication. The user is sending a request to the web site so this is the initial communication and the web site is just responding to it so the traffic will be from the users network to the Internet.

A case where either side can initiate the communication like between two internal interfaces on the FortiGate unit would be a more likely situation to require a policy for each direction.

What is not expressly allowed is denied

One of the fundamental ideas that can be found in just about any firewall is the rule than anything that is not expressly allowed is by default denied. This is the foundation for any strategy of protecting your network. Right

out of the box, once you have your FortiGate device connected into your network and hooked up with your ISP your network is protected. Nothing is getting out or in so it is not very convenient, but you don't have to worry that between the time you hooked it up and the point that you got all of the policies in place that someone could have gotten in and done something to your resources. The reason that this needs to be kept in mind when designing policies is because you cannot assume that any traffic will be allowed just because it makes sense to do so. If you want any kind of traffic to make it past the FortiGate firewall you need to create a policy that will allow that traffic. To maintain the protection of the network should also make sure that the any policy you create allows only the traffic you intend to go only to where you specifically want it to go and when you want it to go there.

Example

You have a web server on your network that is meant to provide a collaborative work environment web site for your employees and a partner company for a project over the course of the next 3 months.

It is theoretically possible to allow connections into your network to any device on that network for any service and at any time. The problem with this is that we might not want just anybody looking at those resources. Sadly, no matter how much it is wished otherwise, not everybody on the Internet can be trusted. Which means we now have to be very specific in our instructions as to what traffic to allow into the network. Each step that we take towards being more specific as to what we allow means that there is that much more that is not allowed and the level of protection of a resources is directly proportional to the amount of traffic that is not allowed. If somebody can't get at it they can't damage or steal it.

Limiting where the traffic is allowed to go to means that other computers on your network besides the web-server are protected.

- Limiting where the traffic is allowed to come from means that, if feasible, you can limit the systems that can access the web server to just employees or the partner company computers.
- Limiting the services to just web traffic means that a malicious person, even if they were connection from a computer at the partner organization could only use the features of web traffic to do anything malicious.
- Limiting the policy to the time span of the project would mean that even if the IT department forgot to remove the policy after the end of the project than no computer from the other company could be used to do anything malicious through the policy that allowed the traffic.

This is just a very basic example but it shows the underlying principles of how the idea that anything not expressly allowed is by default denied can be used to effectively protect your network.

Policy order

Another important factor in how firewall policies work is the concept of precedence of order or if you prefer a more recognizable term, "first come, first served".

It is highly likely that even after only a relatively small number of policies have been created that there will be some that overlap or are subsets of the parameters that the policies use to determine which policy should be matched against the incoming traffic. When this happens there has to be a method to determine which policy should be applied to the packet. The method which is used by most firewalls it based on the order of the sequence of the policies.

If all of the policies were placed in a sequential list the process to match up the packet would start at the top of the list and work its way down. It would compare information about the packet, specifically these points of information:

1. The interface the packet connected to the FortiGate firewall
2. The source address of the packet, and possibly the sending user and device.
3. The destination address of the packet

4. The interface the packet would need to use to get to the destination address based on the routing table
5. The port the packet is destined for
6. The time that the packet connected to the FortiGate

As soon as the a policy is reached that matches all of the applicable parameters, the instructions of that policy are applied and the search for any other matching policies is stopped. All subsequent policies are disregarded. Only 1 policy is applied to the packet.

If there is no matching policy among the policies that have been configured for traffic the packet finally drops down to what is always the last policy. It is an implicit policy. One of a few that are referred to by the term “policy0”. This policy denies everything.

The implicit policy is made up of the following settings:

- Incoming Interface: any
- Source Address: any
- Outgoing Interface: any
- Destination Address: any
- Action: DENY

The only setting that is editable in the implicit policy is the logging of violation traffic.

A logical best practice that comes from the knowledge of how this process works is to make sure that the more specific or specialized a policy is, the closer to the beginning of the sequence it should be. The more general a policy is the higher the likelihood that it could include in its range of parameters a more specifically targeted policy. The more specific a policy is, the higher the probability that there is a requirement for treating that traffic in a specific way.

Example

For security reasons there is no FTP traffic allowed out of a specific subnet so there is a policy that states that any traffic coming from that subnet is denied if the service is FTP, so the following policy was created:

Policy #1

Source Interface	Internal1
Source Address	192.168.1.0/24
Source User(s)	<left at default setting>
Source Device Type	<left at default setting>
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	deny

Now as these things usually go it turns out that there has to be an exception to the rule. There is one very secure computer on the subnet that is allowed to use FTP and once the content has been checked it can them be distributed to the other computer on the subnet. So a second firewall policy is created.

Policy #2

Source Interface	Internal1
Source Address	192.168.1.38/32
Source User(s)	<left at default setting>
Source Device Type	<left at default setting>
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	Allow

By default, a policy that has just been created will be placed last in the sequence so that it is less likely to interfere with existing policies before it can be moved to its intended position. If you look at Policy #2 you will notice that it is essentially the same as Policy #1 exempt for the Source Address and the Action. You will also notice that the Source Address of the Policy #2 is a subset of the Source address in policy #1. This means that if nothing further is done, Policy #2 will never see any traffic because the traffic will always be matched by Policy #1 and processed before it has a chance to reach the second policy in the sequence. For both policies to work as intended Policy #2 needs to be moved to before Policy #1 in the sequence.

Exception to policy order

There is a relevant exception to the normal policy order. Policies with VIPs don't appear to behave the same way. Traffic that is handled by VIPs is processed through the associated policy before the traffic is checked against other policies in the usual top down order.

This only appears inconsistent with the policy order rule because when handling the traffic, firewall policies are not the first thing checked. VIP translations are checked first, and if there is more than one VIP that the traffic fits, it is handled in the top down order that is followed by policies. If the traffic is not claimed by a policy in the VIP translation phase, it is checked against the routing rules. If it passes the routing checks, the traffic is allowed to be controlled by the polices.

This processing of traffic targeting a VIPs only applies if there is a policy that included the VIP and the traffic matches all of the criteria checks. There is no need to worry about creating VIPs that are not controlled by a policy.

There are security implications associated with this behavior. Administrators could assume that a policy will process traffic before it drops down to a policy with a VIP in it. This can allow traffic to pass through the firewall into a part of the network that it was not intended for, if it was to be allowed in at all. The way to prevent traffic being incorrectly allowed through a policy containing a VIP is to have that policy be more restrictive or to have a separate policy containing the same VIP deny the traffic earlier in the sequence.

As proof of the behaviour, look at the following traffic analysis of a packet sent to a VIP. You will see that the packet is translated even before it is allowed to pass through the firewall by a policy.

```

```

Policy identification

When looking at the policy listing it can appear as if the policies are identified by the sequence number in the far left column. The problem is that this number changes as the position of the policy in the sequence changes. The column that correctly identifies the policy, and the value sticks with the policy is the "ID" column. This column is not shown by default in the listing but can be added to the displayed columns by right clicking on the column heading bar and selecting it from the list of possible columns.

When looking in the configuration file the sequence is based upon the order of the policies as they are in the file just as they are in the list in the GUI. However, if you need to edit the policy in the CLI you must use the ID number.

UUID support

Universally Unique Identifier (UUID) attributes have been added to policies to improve functionality when working with FortiManager or FortiAnalyser units. If required, the UUID can be set manually through the CLI.

CLI syntax:

```
config firewall {policy/policy6/policy46/policy64}
   edit 1
      set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
      next
   end
```

Security profiles

Where security policies provide the instructions to the FortiGate unit for controlling what traffic is allowed through the device, the Security profiles provide the screening that filters the content coming and going on the network. Security profiles enable you to instruct the FortiGate unit about what to look for in the traffic that you don't want, or want to monitor, as it passes through the device.

A security profile is a group of options and filters that you can apply to one or more firewall policies. Security profiles can be used by more than one security policy. You can configure sets of security profiles for the traffic types handled by a set of security policies that require identical protection levels and types, rather than repeatedly configuring those same security profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict antivirus protection, traffic between trusted internal addresses might need moderate antivirus protection. To provide the different levels of protection, you might configure two separate profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Security profiles are available for various unwanted traffic and network threats. Each are configured separately and can be used in different groupings as needed. You configure security profiles in the Security Profiles menu and applied when creating a security policy by selecting the security profile type.

There is a separate handbook for the topic of the Security Profiles, but because the Security Profiles are applied through the Firewall policies it makes sense to have at least a basic idea of what the security profile do and how they integrate into the FortiGate's firewall policies. The following is a listing and a brief description of what the security profiles offer by way of functionality and how they can be configured into the firewall policies.

AntiVirus

Antivirus is used as a catch all term to describe the technology for protection against the transmission of malicious computer code sometimes referred to as malware. As anyone who has listened to the media has heard that the Internet can be a dangerous place filled with malware of various flavours. Currently, the malware that is most common in the Internet, in descending order, is Trojan horses, viruses, worms, adware, back door exploits, spyware and other variations. In recent years, not only has the volume of malicious software become greater than would have been believed when it first appeared but the level of sophistication has risen as well.

The Antivirus Filter works by inspecting the traffic that is about to be transmitted through the FortiGate. To increase the efficiency of effort it only inspects the traffic being transmitted via the protocols that it has been

configured to check. Before the data moves across the FortiGate firewall from one interface to another it is checked for attributes or signatures that have been known to be associated with malware. If malware is detected, it is removed.

Web filtering

Malicious code is not the only thing to be wary of on the Internet. There is also the actual content. While the content will not damage or steal information from your computer there is still a number of reasons that would require protection from it.

In a setting where there are children or other sensitive people using the access provided by a connected computer there is a need to make sure that images or information that is not appropriate is not inadvertently displayed to them. Even if there is supervision, in the time it takes to recognize something that is inappropriate and then properly react can expose those we wish to protect. It is more efficient to make sure that the content cannot reach the screen in the first place.

In an organizational setting, there is still the expectation that organization will do what it can to prevent inappropriate content from getting onto the computer screens and thus provoking an Human Resources incident. There is also the potential loss of productivity that can take place if people have unfiltered access to the Internet. Some organizations prefer to limit the amount of distractions available to tempt their workers away from their duties.

The Web filter works primarily by looking at the destination location request for a HTTP(S) request made by the sending computer. If the URL is on a list that you have configured to list unwanted sites, the connection will be disallowed. If the site is part of a category of sites that you have configured to deny connections to the session will also be denied. You can also configure the content filter to check for specific key strings of data on the actual web site and if any of those strings of data appear the connection will not be allowed.

Application control

Application control is designed to allow you to determine what applications are operating on your network and to the also filter the use of these applications as required. Application control is also for outgoing traffic to prevent the use of applications that are against an organization’s policy from crossing the network gateway to other networks. An example of this would be the use of proxy servers to circumvent the restrictions put in place using the Web Filtering.

Intrusion protection (IPS)

Intrusion Prevention System is almost self explanatory. In the same way that there is malware out on the Internet that the network needs to be protected from there are also people out there that take a more targeted approach to malicious cyber activity. No operating system is perfect and new vulnerabilities are being discovered all of the time. An intrusion prevention system is designed to look for activity or behavior that is consistent with attacks against your network. When attack like behavior is detected it can either be dropped or just monitored depending on the approach that you would like to take.

As new vulnerabilities are discovered they can be added to the IPS database so that the protection is current.

Email filtering

Spam or unsolicited bulk email is said to account for approximately 90% of the email traffic on the Internet. Sorting through it is both time consuming and frustrating. By putting an email filter on policies that handle email traffic, the amount of spam that users have to deal with can be greatly reduced.

Data Leak Prevention (DLP)

Data Leak Prevention is used to prevent sensitive information from leaving your network. When people think of security in the cyber-world one of the most common images is that of a hacker penetrating your network and making off with your sensitive information, but the other way that you can lose sensitive data is if someone already on the inside of your network sends it out. This does not have to be an act of industrial espionage. It can just be a case of not knowing the policies of the organization or a lack of knowledge of security or laws concerning privacy.

For instance, a company may have a policy that they will not reveal anyone's Social Security number, but an employee emails a number of documents to another company that included a lengthy document that has a Social Security number buried deep within it. There is not malicious intent but if the information got out there could be repercussions.

If an organization has any information in a digital format that it cannot afford for financial or legal reasons, to leave its network, it makes sense to have Data Leak Prevention in place as an additional layer of protection.

VoIP

Voice over IP is essentially the protocols for transmitting voice or other multimedia communications over Internet Protocol networks such as the Internet. The Security Profiles VoIP options apply the SIP Application Level Gateway (ALG) to support SIP through the FortiGate unit. The SIP ALG can also be used to protect networks from SIP-based attacks.

ICAP

Internet Content Adaptation Protocol (ICAP) off loads HTTP traffic to another location for specialized processing. The purpose of this module when triggered is to send the incoming HTTP traffic over to a remote server to be processed thus taking some of the strain off of the resources of the FortiGate unit. The reasons for the specialized process could be anything from more sophisticated Antivirus to manipulation of the HTTP headers and URLs.

EndPoint control

EndPoint Control makes sure that certain standards are kept. When a computer on the Internet becomes connected to the FortiGate unit by VPN that computer is now part of the same network and therefore needs to be subject to the same levels of protection, not only to protect the computer but the network. In the EndPoint Control section you can set the minimum standards for things like AntiVirus software and VPN software.

Proxy option components

Any time a security profile that requires the use of a proxy is enabled the Proxy Options field will be displayed. Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out and so the Proxy Options are there to define the parameters of how the traffic will be processed and to what level the traffic will be processed. In the same way that there can be multiple security profiles of a single type there can also be a number of unique Proxy Option profiles so that as the requirements for a policy differ from one policy to the next you can also configure a different Proxy Option profile for each individual policy or you can use one profile repeatedly.

The Proxy Options refer to the handling of the following protocols:

- HTTP
- SMTP

- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- IM

The configuration for each of these protocols is handled separately.

It should also be noted that these configurations apply to only the Security Profiles Proxy-based processes and not the Flow-based processes.

The use of different proxy profiles and profile options

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

Oversized file log

This setting is for those that would like to log the occurrence of oversized files being processed. It does not change how they are processed it only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for what is considered to be an oversized file is located in the Oversized File / Email Threshold that is found in some of the protocol options for the Proxy Options.

Protocol port mapping

While each of the protocols listed has a default TCP port that is commonly used, the level of granularity of control on the FortiGate firewall allows that the port used by the protocols can be individually modified in each separate Profile. It can also be set to inspect any port with flowing traffic for that particular protocol. The headers of the packets will indicate which protocol generated the packet. To optimize the resources of the unit the mapping and inspection of protocols can be enabled or disabled depending on your requirments.

Comfort Clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The comfort client feature to mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the

transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

If there is evidence of an infection the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Oversized file/email threshold

This is another feature that is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could not only overwhelm the memory of the FortiGate, especially if there were other large files being downloaded at the same time, but could exceed it as well. For this reason, how to treat large files needs to be addressed.

A threshold is assigned to determine what should be considered an oversize file or email. This can be set at any size from 1 MB to 50 MB. Any file or email over this threshold will not be processed by the Antivirus Security Profiles. Once a file is determined to be oversized it must be then determined whether to allow it or to block it.

These settings are not a technical decision but a policy one that will depend on your comfort level with letting files into your network. As there often is, there is a compromise between convenience or ease of use and security. If you want to go for a high peace of mind level you can configure the firewall to block oversized files and thus no files would be coming into the network that have not been scanned. If you are looking for optimizing the memory of the FortiGate unit and making sure that everybody is getting the files they want, you can lower the threshold and allow files that are over the threshold.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

Chunked bypass

The HTTP section allows the enabling of “Chunked Bypass”. This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned this means that there is a faster initial response to HTTP requests. From a security stand point it means that the content will not be held in the proxy as an entire file before proceeding.

Allow fragmented messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of allowing this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

Append email signature

The Append Email Signature is used when an organization would like to ensure that over and above our in this case underneath the existing personal signatures of the sender, all of the emails going out of their network have the appropriate “boilerplate”, for lack of a better term. These appended emails do not replace existing signatures. They are as the feature states, appended to the email.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don’t print out emails
- For questions regarding the purchasing of our products please call…

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

SSL/SSH inspection

While the profile configuration for this is not found in the Security Profiles section but in the Policy Section, it is set in the policy along with the security profiles. This sort of analysis is some times referred to as deep scanning.

Deep Inspection works along the following lines. If your FortiGate unit has the correct chipset it will be able to scan SSL encrypted traffic in the same way that regular traffic can be scanned. The FortiGate firewall will essentially receive the traffic on behalf of the client and open up the encrypted traffic. Once it is finished it re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. By enabling this feature, it allows the FortiGate firewall to filter on traffic that is using the SSL encrypted protocol.

The encrypted protocols that can be inspected are:

- HTTPS
- SMTPS
- POP3S
- IMAPS
- FTPS

Before the invention of SSL inspection, scanning regular web traffic can be circumvented by using the prefix https:// instead of http:// in the URL. SSL inspection prevents this circumvention. However, because when the encrypted traffic is decrypted it has to be re-encrypted with the FortiGate’s certificate rather than the original certificate it can cause errors because the name on the certificate does not match the name on the web site.

At one point deep inspection was something that was either turned on or off. Now individual deep inspection profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic.
- Configure which SSL protocols will be inspected.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites will be exempt from SSL inspection
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not SSH traffic will be inspected.

HTTP Strict Transport Security (HSTS) Protocol

HSTS is a protocol used by Google and other web browsers to prevent man-in-the-middle attacks.

When performing deep inspection, the FortiGate intercepts the https traffic and would send its own self-signed CA certificate to the browser. If the browser is configured to use HSTS connections, it would refuse the FortiGate CA certificate since it is not on the trusted list for Google servers.

To keep the CA certificate from being refused, the HSTS settings should be cleared from the browser. Instructions for this vary between browsers.

Inspection exemption

When you are using a browser to visit SSL encrypted sites and we are using a certificate that does not match the certificate of the site, we are presented with a warning message and the option of continuing, using the untrusted certificate, or terminating the session. However, there are a number of applications that use SSL encrypted traffic. If the application detects SSL traffic that wasn't signed with a certificate that it trusts it will not allow the traffic. The applications do not give the option to manually indicate that we trust the certificate or the site.

If the option is available, the customer may choose to import needed SSL certificates into Local Certificates and configure a policy for communication for that application.

The assist in preventing loss of access to these site but still enabling the SSL inspection of the rest of the internet traffic, a method of exempting either Website categories or specific sites has been developed. To exempt a large group of sites the profile can be configure to exempt FortiGuard Categories. There are 3 of these categories preselected due to the high likelihood of issues with associated applications with the type of websites included in these categories.

- Heath and Wellness
- Personal Privacy
- Finance and Banking

Other more specific websites can be added to the exemption list by creating addresses for them at **Policy & Objects > Objects > Addresses**. The adding of addresses is done by selection from a drop down menu. There is an option at the bottom of the list to create a new address, but otherwise only preconfigured addresses that are configured to be on the "Any" interface will be available for selection.

Examples of sites that you may want to configure for exemption so that there will be no interference due to certificate issues:

Apple

- *.appstore.com
- *.apple.com
- *.itunes.apple.com
- *.icloud.com
- swscan.apple.com

Dropbox

- *.dropbox.com

Skype

- *.messenger.live.com

Windows Updates

- update.microsoft.com

Allow invalid SSL certificate

This setting was something that used to be part of the **Proxy Options**, but now that SSL inspection has it's own configuration setting it is configured with those. It might seem like a straight forward decision that the allowing of invalid SSL certificates must be bad and therefore should not be allowed, but there can be some reasons that should be considered. The issues at hand are the reasons to use a SSL certificate and the reasons that a certificate will be considered invalid.

At a purely technical level, a properly formed certificate will encrypt the data so that it can only be read by the intended parties and not be read by anyone sniffing traffic on the network. For this reason, people will often use self-signed certificates. These self signed certificates are free and will encrypt the data just as well as those purchased from any of the big vendors of certificates, but if they are not listed as an approved Certificate Authority (CA) the certificates will be considered invalid.

On the other hand, one of the services the vendors provide is verification of identity of those that purchase their certificates. This means that if you see a valid certificate from a site that identified itself as being from "valid-company.com" that you can be reasonably sure that the site does belong to that company and not a false site masquerading as being part of that company.

Creating or editing an SSL/SSH inspection profile

1. Go to **Policy & Objects > Policy > SSL/SSH Inspection**.
   This will open to one of the existing profiles.
   The links for the actions are located in the upper right hand corner of the window.
   - To view a list of the exiting profiles select the List icon (a page) at the far right.
   - To clone an existing profile, select the Clone icon (one page behind another), second from the right
   - To create a new profile, select the Create New icon ("+ "symbol), third from the right.
   - To view or edit an existing profile, choose it from the dropdown menu field.
2. **Name Field:**
   Give the Profile an easily identifiable name that references its intent.

3. **Comments Field:**
   Enter any additional information that might be needed by administrators, as a reminder of the profile's purpose and scope.
4. **SSL Inspection Options:**
   a. Enable SSL Inspection of:
   - Multiple Clients Connecting to Multiple Servers - Use this option for generic policies where the destination is unknown.
   - Protecting SSL Server - Use this option when setting up a profile customized for a specific SSL server with a specific certificate.

   b. CA Certificate
   Use the drop down menu to choose which one of the installed certificates to use for the inspection of the packets.

   c. Inspection Method
   The options here are:
   - SSL Certificate Inspection - only inspects the certificate, not the contents of the traffic.
   - Full SSL Inspection - inspects all of the traffic.

   d. Inspect All Ports
   Enable the ability to inspect all ports by checking the box. If the feature is not enabled, specify in the field next to the listed protocols, the port through which that protocols traffic will be inspected. Traffic of that protocol going through any other port will not be inspected.
5. **Exempt from SSL Inspection:**
   Use the dropdown menus in this section to specify either a FortiGuard Web Category or addresses that will be exempt from SSL inspection.
   a. Web Categories
   By default the categories of Health and Wellness, Personal Privacy, and Finance and Banking have been added as these are one that are most likely to have applications that will require a specific certificate.

   b. Addresses
   These can be any of the Address objects that have an interface of "Any".
6. **SSH Inspection Options:**
   a. SSH Deep Scan
   Toggle the grey on button so that it is:
   Greyed out to disable the feature
   Opaque and vibrate to enable the feature

   b. SSH Port
   The available options are:
   - **Any** - choosing this option will search all of the traffic regardless of service or TCP/IP port for packets that conform to the SSH protocol
   - **Specify** - choosing this option will restrict the search for SSH protocol packets to the TCP/IP port number specified in the field. This is not as comprehensive but it is easier on the performance of the firewall.

   d. Protocol Actions
   - Exec - Block, Log or neither. Select using check boxes.
   - Port-Forward - Block, Log or neither. Select using check boxes.
   - SSH-Shell - Block, Log or neither. Select using check boxes.
   - X11-Filter - Block, Log or neither. Select using check boxes.

7. **Common Options:**
   a. Allow Invalid SSL Certificates
   Check the box to enable the passing of traffic with invalid certificate
   b. Log Invalid Certificates
   Check the box to have the Logging function record traffic sessions that contained invalid certificates

The **Enable SSH Deep Scan** feature is enabled by default when creating a new SSL/SSH Inspection profile. There are situations were this feature can cause issues so be sure that you would like it enabled before applying it.

The context location for configuring the SSL/SSH Inspection in the CLI is:

```
config firewall ssl-ssh-profile
```

Viewing firewall policies

When you first go into the Policy window, found by going to Policy > Policy > Policy, you will see a table with a menu bar across the top. The menu bar will have the following items:

At the top left:

- Create New (with a “+” sign on the left and a downward pointing triangle on the right)
- Clone
- Delete
- Column Settings
- Filter Settings

At the top right:

- Section View
- Global View

The items at the top right with their radio buttons represent the 2 potential views that the policies can be displayed in.

The Global View shows all of the policies in the order of their sequence. With the default settings you will be able to see the sequence number in a column close to the left side of the table.

The Section view is similar to the Global View except that as the name implies it is divided into sections. By default the sections are based on the paths between the interfaces. These can be referred to as “interface pairings”. For instance, all of the policies referencing traffic from WAN1 to DMZ will be in one section. The policies referencing traffic from DMZ to WAN1 will be in another section.

The sections are collapsible so that you only need to look at the sections with policies you are interested in. It is possible to add customized subsections within the default sections of interface pairings. This would be useful in a situation where you have a lot of policies and would like to further compartmentalize them by common attributes so that things are easier to find.

The default column headings are:

- [Check box icon]
- Seq.#
- Source
- Destination
- Authentication
- Schedule
- Service
- Action
- Log

The column that are shown are configurable. All but the first 2 can be removed or their position changed. There are also a number of other columns that display information about the policies that can be added. One of the more useful ones that can be added is the ID column. The reason for adding this one is that policies are referenced by their ID number for simplicity and ease of administration. If you are looking in the CLI you will see that the only designation for a policy is its number and if you wish to change the order of a policy you will be asked to move it before or after another policy by referencing its number.

How “Any” policy can remove the section view

The FortiGate unit will automatically change the view on the policy list page to Global View whenever a policy containing “any” in the Source interface/zone or Destination interface/zone is created. If the Section View is greyed out it is likely that one or more of the policies has “any” as a Source or Destination interface.

With the use of the “any” the policy should go into multiple sections because it could effectively be any of a number of interface pairings. As mentioned, policies are sectioned by using the interface pairings (for example, port1 -> port2) and each section has its own specific policy order. The order in which a policy is checked for matching criteria to a packet’s information is based solely on the position of the policy within its section or within the entire list of policies as a whole but if the policy is in multiple sections at the same time there is no mechanism for placing the policy in a proper order within all of those sections at the same time because it is a manual process and there is no parameter to compare the precedence of one section or policy over the other. Thus a conflict is created. In order to resolve the conflict the FortiGate firewall removes that aspect of the sections so that there is no need to compare and find precedence between the sections and it therefore has only the Global View to work with.

Security policy configuration extensions

When first creating the policy the configuration form will ask for a choice between the policy types of Firewall or VPN, Firewall being the default. Choosing whether or not to leave the selection as Firewall is straight forward. If the policy is not a policy based VPN policy then it is a Firewall policy type.

There are essentially 2 types of VPN connections, Interface Based and Policy Based. In an Interface Based VPN tunnel a logical interface is created that can be seen as an interface by the policies in the same way that any of the physical interfaces can be seen. Therefore to govern the traffic a regular policy will work. The policy based VPN tunnels work slightly different and therefore need a slightly different policy configuration. For a more detail explanation of the difference between the types of VPN tunnels refer to the VPN documentation found in the VPN handbooks or in the VPN section of the Complete Administration Guide.

Once either the Firewall or the VPN type has been chosen there is then a choice between one of subtypes for each of the Policy types. For the Firewall type of policy the subtypes are:

- Address
- User Identity

- Device Identity

The Address subtype refers to policies where access through the FortiGate firewall is dependant on the source location of the addresses of the devices involved in the traffic matched to the policy.

The User Identity subtype refers to policies where access through the FortiGate firewall is dependant on the users credentials or Identity.

The Device Identity subtype refers to policy where access through the FortiGate firewall is dependant on the specific device being used based on the MAC address of the device or belonging to a group of devices that are based on device types or belonging to custom made groups.

For the VPN type the subtypes are:

- IPsec
- SSL-VPN

As expected the two subtypes are the two different types of VPN tunnels that the FortiGate firewall supports in a policy based configuration.

Identity-based policies

Identity based policies are ones in which there is the additional component of either an account identity or device identity. The inclusion of one or both of these components adds an extra dimension of complexity to working with these policies in the context of the other policies so while the extra security and granularity of control are beneficial, extra care must be taken when configuring the policies themselves and how they are positioned in the policy sequence. The actual configuration of these identities are explained in detail in the Authentication Handbook.

Identity-based security policies are usually configured for IPsec or SSL VPN traffic since this type of traffic usually requires authentication from network users.

Identity-based policy positioning

In non-identity based policies, if non of the 6 mandatory policy parameters matches the header of the traffic packets the parameters are compared against the next policy in sequence. Because those parameters are mandatory there is always a value to test against and whether or not the policy applies is certain. The fact that the identity parameters are not required makes knowing whether or not the correct policy will be applied less obvious.

Originally, the identity aspect of a policy was an entire sub-policy checking sequence within each policy, including its own 0 policy at the end of the sequence. If all of the other parameters match the policy would then compare the traffic's identity with the list of identity groups in the policy starting at the beginning of the sequence and going through them until an identity was found that matched and then the rules for that identity group would be applied. If the traffic's identity did not match any of those listed in the policy it go to the last identity in the policy would be everyone and the Action would be deny.

The identity aspects of policies have now been incorporated in a single flat configuration that makes them a fundamental part of the policy rather than something that is added to the policy. This is simpler and allows for more complex combinations of address identification, user authentication and device determination that were not possible with previous policy configurations. Both user groups and device groups can be part of the same policy. Because the identity aspects are optional, more flexibility in creating policies that use authentication is possible.

Identity fall through rules

The fall through rules for policies in 5.2 have changed so that they are more in keeping with the practices of other vendors. This makes it easier for users used to other firewalls to configure the policies and it also makes it simpler to convert the policies of other firewalls to be used on a FortiGate firewall.

Previously, if traffic reached an identity policy and the user or device was not a member of one of the groups specified it would fall through to the implicit deny all policy. This meant that any traffic that reached that policy would have to be authenticated and a member of one of the listed groups. If the 6 required parameters matched, the traffic would not be getting past this policy.

The approach is now to treat the the identity parameters, if they exist, the same as the other parameters, in that if they do not match any listed in the policy, the traffic drops down to the next policy.

Example:

There are three policies where all the parameters are the same except:

- Policy # 1 - Source User Group A is assigned profile A
- Policy # 2 - Source User Group B s assigned profile B
- Policy # 3 - Source User(s) and Source Device Type are empty

Traffic that matches all of the required parameters will be processed as follows:

- Traffic authenticated as being from User Group A will be processed by Policy # 1.
- Traffic authenticated as being from User Group B will be processed by Policy # 2.
- Traffic with no authenticated users will be processed by Policy # 3.
- Traffic authenticated as being from User Group C will be processed by Policy # 3.

In the methodology before FortiOS 5.2, traffic authenticated as being User Group B, User Group C or no authenticated user at all would have been stopped at Policy # 1.

The CLI command “fall-through-unauthenticated” that was added in 5.0.1 attempted to allow a process similar to this, but only applied to unathenticated traffic and not authenticated traffic that didn’t match the list of groups is the sub-policy. The current methodology is not subject to the same limitation and alleviates the need for the function of this command so the command has been removed from the CLI.

Implicit protocols

In previous versions of the firmware, the protocols that were used to authenticate such as HTTP, HTTPS, FTP, and Telnet, were supported on the policy whether or not they were included in the supported services. In 5.2, the protocol needed to authenticate needs to be included in the list of allowed services in order the the authentication to take place.

For example, if you have a VIP coming into your network that is for connecting to some security webcams located in your data center that use custom services or ports to connect to, if you are using an identity policy you would also have to include HTTP or HTTPS in the services list in order to actually authenticate.

Another formerly implicit protocol that is not supported automatically in 5.2 is port 53 (DNS). If you are limiting the services of a protocol to web based protocols such as HTTP or HTTPS don’t forget to to add DNS so that the domain names can be resolved.

When upgrading the firmware from version 5.0.x to 5.2.x, a policy with either an identity or device sub-policy will automatically convert from a single policy with sub-policies to a separate policy for each identity based sub-policy.

VPN policies

At one point, if you wanted to have secure digital communications between 2 points a private network would be created. This network would only allow the people that were intended to get the communications on it. This is very straightforward if the 2 points are in the same room or even in the same building. It can all be done physically. If you are supposed to be on the secure network

VPNs are an answer to one of today's biggest concerns, how to make digital communications secure between to points that must communicate over the Internet which anybody can have access to

IPsec policies

IPsec policies allow IPsec VPN traffic access to the internal network from a remote location. These policies include authentication information that authenticates users and user group or groups. These policies specify the following:

- the FortiGate firewall interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate firewall interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optional: a schedule that restricts when the VPN can operate, and services (or types of data) that can be sent.

For a route-based (interface mode) VPN, you do not configure an IPsec security policy. Instead, you configure two regular ACCEPT security policies, one for each direction of communication, with the IPsec virtual interface as the source or destination interface, as appropriate.

Interface policies

Interface policies are implemented before the "security" policies and are only flow based.

This feature allows you to attach a set of IPS policies with the interface instead of the forwarding path, so packets can be delivered to IPS before entering firewall. This feature is used for following IPS deployments:

- One-Arm: by defining interface policies with IPS and DoS anomaly checks and enabling sniff-mode on the interface, the interface can be used for one-arm IDS;
- IPv6 IPS: IPS inspection can be enabled through interface IPv6 policy. Only IPS signature scan is supported in FortiOS 5.2. IPv6 DoS protection is not supported;
- Scan traffics that destined to FortiGate;
- Scan and log traffics that are silently dropped or flooded by Firewall or Multicast traffic.

IPS sensors can be assigned to an interface policy. Both incoming and outgoing packets are inspected by IPS sensor (signature).

Here is an example of an interface policy,

```
config firewall interface-policy
   edit 1
      set status enable
```

```
        set interface "port14"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set application-list-status disable
        set ips-sensor-status enable
        set ips-sensor "default"
        set av-profile-status disable
        set webfilter-profile-status disable
        set spamfilter-profile-status disable
        set dlp-sensor-status disable
        set label "Port 14 Interface Policy"
    next
end
```

DoS protection

Denial of Service (DoS) policies are primarily used to apply DoS anomaly checks to network traffic based on the FortiGate interface it is entering as well as the source and destination addresses. DoS checks are a traffic anomaly detection feature to identify network traffic that does not fit known or common traffic patterns and behavior. A common example of anomalous traffic is the denial of service attack. A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, so that legitimate users can no longer use it.

DoS policies are similar to firewall policies except that instead of defining the way traffic is allowed to flow, they keep track of certain traffic patterns and attributes and will stop traffic displaying those attributes. Further, DoS policies affect only incoming traffic on a single interface. You can further limit a DoS policy by source address, destination address, and service.

DoS configurations have been changed a couple of times in the past. In FortiOS 4.0, DoS protection was moved to the interface policy, so when it is enabled, it is the first thing checked when a packet enters FortiGate. Because of this early detection, DoS policies are a very efficient defence that uses few resources. Denial of service attacks, for example, are detected and its packets dropped before requiring security policy look-ups, antivirus scans, and other protective but resource-intensive operations.

A DoS policy examines network traffic arriving at an interface for anomalous patterns usually indicating an attack. This does not mean that all anomalies experience by the firewall are the result of an intentional attack.

Because an improperly configured DoS anomaly check can interfere with network traffic, no DoS checks are preconfigured on a factory default FortiGate unit. You must create your own before they will take effect. Thresholds for newly created sensors are preset with recommended values that you can adjust to meet the needs of your network.

To create a Denial of Service policy determine if it needs to be an IPv4 or IPv6 policy, then goto:

Policy & Objects > Policy > DoS Policy for IPv4.

Policy & Objects > Policy > IPv6 DoS Policy for IPv6.

It is important to know normal and expected network traffic before changing the default anomaly thresholds. Setting the thresholds too low could cause false positives, and setting the thresholds too high could allow otherwise avoidable attacks.

Settings used in configuring DoS

Incoming interface

The interface to which this security policy applies. It will be the that the traffic is coming into the firewall on.

Source address

This will be the address that the traffic is coming from and must be a address listed in the Address section of the Firewall Objects. This can include the predefined “all” address which covers any address coming in on any interface. Multiple addresses or address groups can be chosen

Destination address

This will be the address that the traffic is addressed to. In this case it must be an address that is associated with the firewall itself. For instance it could be one of the interface address of the firewall, a secondary IP address or the interface address assigned to a Virtual IP address. Just like with the Source Address this address must be already configured before being used in the DoS policy.Multiple addresses, virtual IPs or virtual IP groups can be chosen.

Service

While the Service field allows for the use of the ALL service some administrators prefer to optimize the resources of the firewall and only check on the services that will be answered on an interface. Multiple services or service groups can be chosen.

Anomalies

The anomalies can not be configured by the user. They are predefined sensors set up for specific patterns of anomalous traffic

The anomalies that have been predefined for use in the DoS Policies are:

Anomaly Name	Description	Recommended Threshold
tcp_syn_flood	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
tcp_port_scan	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
tcp_src_session	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
tcp_dst_session	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_flood	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_scan	If the number of UDP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_src_session	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_dst_session	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
icmp_flood	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
icmp_sweep	If the number of ICMP packets originating from one source IP address exceeds the configured threshold value, the action is executed.	100 packets per second.
icmp_src_session	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions

Anomaly Name	Description	Recommended Threshold
icmp_dst_session	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	3000 concurrent sessions
ip_src_session	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
ip_dst_session	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
sctp_flood	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
sctp_scan	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
sctp_src_session	If the number of concurrent SCTP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions
sctp_dst_session	If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

Status

The status field is enabled to enable the sensor for the associated anomaly. In terms of actions performed there is no difference between disabling a sensor and having the action as “Pass” but by disabling sensors that are not being used for blocking or logging you can save some resources of the firewall that can be better used elsewhere.

Logging

Regardless of whether the traffic is blocked or passed through the anomalous traffic will be logged.

Pass

Allows the anomalous traffic to pass through unimpeded.

Block

For Thresholds based on the number of concurrent sessions blocking the anomaly will not allow more than the number of concurrent sessions set as the threshold.

For rate based thresholds where the threshold is measured in packets per second, the Action setting “Block” prevents the overwhelming of the firewall by anomalous traffic in one of 2 ways. Setting which of those 2 ways will be issued is determined in the CLI.

- continuous - blocks any packets that match the anomaly criteria once the threshold has been reached
- periodical - allows matching anomalous traffic up to the rate set by the threshold.

If the period for a particular anomaly is 60 seconds, such as those where the threshold is measured in concurrent sessions, after the 60 second timer has expired, the number of allowed packets that match the anomaly criteria is reset to zero. This means that if you allow 10 sessions through before blocking, after the 60 seconds is up, another 10 will be allowed. The attrition of sessions from expiration should keep the allowed sessions from reaching the maximum.

To set the type of block action for the rate based anomaly sensors:

```
config ips global
   set anomaly-mode continuous
   set anomaly-mode periodical
end
```

Threshold

The threshold can be either in terms of concurrent session or in packets per second depending on which sensor is being referred to.

One-arm IDS

Interface-based policy only defines what and how IPS functions are applied to the packets transmitted by the interface. It works no matter if the port is used in a forwarding path or used as an One-Arm device.

To enable One-Arm IDS, the user should first enable sniff-mode on the interface,

```
config system interface
   edit port2
      set ips-sniffer-mode enable
   next
end
```

Once sniff-mode is turned on, both incoming and outgoing packets will be dropped after IPS inspections. The port can be connected to a hub or a switch's SPAN port. Any packet picked up by the interface will still follow the interface policy so different IPS and DoS anomaly checks can be applied.

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
   edit 1
      set interface "port1"
      set srcaddr6 "all"
      set dstaddr6 "all"
      set service6 "ANY"
      set ips-sensor-status enable
      set ips-sensor "all_default"
   next
end
```

Traffic destined to the FortiGate unit

IPS enabled in firewall policies can only inspect the traffic pass through FortiGate unit, not the traffic destined to FortiGate unit. Enabling IPS in interface-policy allows IPS to pick up any packet on the interface so it is able to inspect attacks targeting FGT.

Dropped, flooded, broadcast, multicast and L2 packets

In many evaluation or certification tests, FortiGate firewall is often required to log any packets dropped by the firewall. In most of cases, these packets are of invalid headers so firewall just drops them silently. It is natural to forward all these packets to IPS first so FortiGate firewall is able to generate logs for invalid packets.

Flooded, broadcast and multicast traffics do not reach any of services in the forwarding path. They can be inspected by the interface policy as long as they match the addresses defined. Potentially, L2 packets can also be sent to IPS for inspection through interface-policy, but it is not enabled in FortiOS 5.2.

GUI and CLI

Now in FortiGate, there are two places that IPS can be enabled, in a firewall policy and in an interface policy. In the firewall policy implementation, IPS sensor can be configured in both CLI and GUI. When adding an IPS sensor to an interface policy it must be done through the CLI. There is no GUI input window for the “Interface Policy”. There is however, a DoS Policy section in the GUI.

Local-In policies

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Security policies control the flow of traffic through the FortiGate unit. The FortiGate unit also includes the option of controlling internal traffic, that is, management traffic.

Each interface includes an allow access configuration to allow management access for specific protocols. Local policies are set up automatically to allow all users all access. Local-in policies takes this a step further, to enable or restrict the user with that access. This also extends beyond the allow access selection.

Local-in policies are configured in the CLI with the commands:

```
config firewall local-in-policy
   edit <policy_number>
      set intf <source_interface>
      set srcaddr <source_address>
```

```
      set dstaddr <destination_address>
      set action {accept | deny}
      set service <service name>
      set schedule <schedule_name>
   end
```

For example, you can configure a local-in policy so that only administrators can access the FortiGate unit on weekends from a specific management computer at 192.168.21.12, represented by the address object mgmt-comp1, using SSH on port 3 (192.168.21.77 represented by the address object FG-port3) using the Weekend schedule which defines the time the of access.

```
config firewall local-in-policy
   edit <1>
      set intf port3
      set srcaddr mgmt-comp1
      set dstaddr FG-port3
      set action accept
      set service SSH
      set schedule Weekend
   end
```

You can also disable a policy should there be a requirement to turn off a policy for troubleshooting or other purpose. To disable a policy enter the commands:

```
config firewall local-in-policy
   edit <policy_number>
      set status disable
   end
```

Use the same commands with a status of enable to use the policy again.

Local-in policies are also supported for IPv6 by entering the command

```
config firewall local-in-policy6.
```

Security policy 0

Any security policy that is automatically added by the FortiGate unit has a policy ID number of zero (0). The most common reasons the FortiGate unit creates this policy is:

- The IPsec policy for FortiAnalyzer (and FortiManager version 3.0) is automatically added when an IPsec connection to the FortiAnalyzer unit or FortiManager is enabled.
- The policy to allow FortiGuard servers to be automatically added has a policy ID number of zero.
- The (default) drop rule that is the last rule in the policy and that is automatically added has a policy ID number of zero.
- When a network zone is defined within a VDOM, the intra-zone traffic set to allow or block is managed by policy 0 if it is not processed by a configured security policy.

This policy can appear in logs but will never appear in the security policy list, and therefore, can never be repositioned in the list.

When viewing the FortiGate firewall logs, you may find a log field entry indicating policyid=0. The following log message example indicates the log field policyid=0 in bold.

```
2008-10-06 00:13:49 log_id=0022013001 type=traffic subtype=violation pri=warning
    vd=root SN=179089 duration=0 user=N/A group=N/A rule=0 policyid=0 proto=17
    service=137/udp app_type=N/A status=deny src=10.181.77.73 srcname=10.181.77.73
    dst=10.128.1.161 dstname=10.128.1.161 src_int=N/A dst_int="Internal" sent=0 rcvd=0
    src_port=137 dst_port=137 vpn=N/A tran_ip=0.0.0.0 tran_port=0
```

Deny policies

Deny security policies deny traffic that is coming into the network. The FortiGate unit automatically blocks traffic that is associated with a deny security policy.

Deny security policies are usually configured when you need to restrict specific traffic, for example, SSH traffic. Deny security policies can also help when you want to block a service, such as DNS, but allow a specific DNS server.

There is a disparity in the effectiveness of deny policies. Only deny policies that contain VIPs will block traffic directed at those VIPs. Policies with VIPs are processed before other polices, so using a deny policy earlier in the list will not work. For more on this topic, read the "Exception to policy order" on page 1009.

Accept policies

Accept security policies accept traffic that is coming into the network. These policies allow traffic through the FortiGate unit, where the packets are scanned, translated if NAT is enabled, and then sent out to its destination.

Accept security policies are the most common security policies that are created in FortiOS. These security policies are basic policies, such as allowing Internet access, as well as complex policies, such as IPsec VPN.

Fixed port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

From the CLI you can enable fixedport when configuring a security policy for NAT policies to prevent source port translation.

```
config firewall policy
   edit <policy-id>
      ...
      set fixedport enable
      ...
   end
```

However, enabling fixedport means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

Endpoint security

Endpoint security enforces the use of the FortiClient End Point Security (FortiClient and FortiClient Lite) application on your network. It can also allow or deny endpoints access to the network based on the application installed on them.

By applying endpoint security to a security policy, you can enforce this type of security on your network. FortiClient enforcement can check that the endpoint is running the most recent version of the FortiClient application, that the antivirus signatures are up-to-date, and that the firewall is enabled. An endpoint is usually often a single PC with a single IP address being used to access network services through a FortiGate unit.

With endpoint security enabled on a policy, traffic that attempts to pass through, the FortiGate unit runs compliance checks on the originating host on the source interface. Non-compliant endpoints are blocked. If someone is browsing the web, the endpoints are redirected to a web portal which explains the non-compliance and provides a link to download the FortiClient application installer. The web portal is already installed on the FortiGate unit, as a replacement message, which you can modify if required.

Endpoint Security requires that all hosts using the security policy have the FortiClient Endpoint Security agent installed. Currently, FortiClient Endpoint Security is available for Microsoft Windows 2000 and later only.

For more information about endpoint security, see the Security Profiles chapter in the FortiOS Handbook.

Traffic logging

When you enable logging on a security policy, the FortiGate unit records the scanning process activity that occurs, as well as whether the FortiGate unit allowed or denied the traffic according to the rules stated in the security policy. This information can provide insight into whether a security policy is working properly, as well as if there needs to be any modifications to the security policy, such as adding traffic shaping for better traffic performance.

Depending on what the FortiGate unit has in the way of resourses, there may be advantages in optimizing the amount of logging taking places. This is why in each policy you are given 3 options for the logging:

- **No Log** - Does not record any log messages about traffic accepted by this policy.
- **Log Security Events** - records only log messages relating to security events caused by traffic accepted by this policy.
- **Log all Sessions** - records all log messages relating to all of the traffic accepted by this policy.

  Depending on the the model, if the Log all Sessions option is selected there may be 2 additional options. These options are normally available in the GUI on the higher end models such as the FortiGate 600C or larger.
  - **Generate Logs when Session Starts**
  - **Capture Packets**

You can also use the CLI to enter the following command to write a log message when a session starts:

```
config firewall policy
   edit <policy-index>
      set logtraffic-start
   end
```

Traffic is logged in the traffic log file and provides detailed information that you may not think you need, but do. For example, the traffic log can have information about an application used (web: HTTP.Image), and whether or not the packet was SNAT or DNAT translated. The following is an example of a traffic log message.

```
2011-04-13
05:23:47
log_id=4
type=traffic
subtype=other
pri=notice
vd=root
status="start"
src="10.41.101.20"
srcname="10.41.101.20"
src_port=58115
dst="172.20.120.100"
dstname="172.20.120.100"
```

```
dst_country="N/A"
dst_port=137
tran_ip="N/A"
tran_port=0
tran_sip="10.31.101.41"
tran_sport=58115
service="137/udp"
proto=17
app_type="N/A"
duration=0
rule=1
policyid=1
sent=0
rcvd=0
shaper_drop_sent=0
shaper_drop_rcvd=0
perip_drop=0
src_int="internal"
dst_int="wan1"
SN=97404 app="N/A"
app_cat="N/A"
carrier_ep="N/A"
```

If you want to know more about logging, see the Logging and Reporting chapter in the FortiOS Handbook. If you want to know more about traffic log messages, see the FortiGate Log Message Reference.

Quality of service

The Quality of Service (QoS) feature allows the management of the level of service and preference given to the various types and sources of traffic going through the firewall so that the traffic that is important to the services and functions connecting through the firewall gets the treatment required to ensure the level of quality that is required.

QoS uses the following techniques:

Traffic policing	Packets are dropped that do not conform to bandwidth limitations
Traffic Shaping	Assigning minimum levels of bandwidth to be allocated to specific traffic flows to guarantee levels of servers or assigning maximum levels of bandwidth to be allocated to specific traffic flows so that they do not impede other flows of traffic.

This helps to ensure that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Traffic shaping also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows that are greater than the maximum rate are subject to traffic policing.

Queuing

Assigning differing levels priority to different traffic flows so that traffic flows that are adversely effected by latency are prevented from being effected by traffic flows that are not subject to the effects of latency. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

An example of where you would want to use something like this is if you had competing traffic flows of Voice over IP traffic and email traffic. The VoIP traffic is highly susceptible to latency issues.If you have a delay of a few seconds it is quickly noticeable when it is occurring. Email on the other hand can have a time delay of much longer and it is highly unlikely that it will be noticed at all.

By default, the priority given to any traffic is high, so if you want to give one type of traffic priority over all other traffic you will need to lower the priority of all of the other traffic.

Policy Monitor

Once policies have been configured and enabled it is useful to be able to monitor them. To get an overview about what sort of traffic the policies are processing go to Policy > Monitor > Policy Monitor.

The window is separated into two panes.

Upper pane

The upper pane displays a horizontal bar graph comparing the **Top Policy Usage** based on one of the following criteria:

- Active Sessions
- Bytes
- Packets

The criteria that the displayed graph is based on can be selected from the drop down menu in the upper right corner of the pane. The field name is **Report By:**.

The bars of the graph are interactive to an extent and can be used to drill down for more specific information. If you hover the cursor over the bar of the graph a small popup box will appear displaying more detailed information. If the bar of the graph is selected an entirely new window will be displayed using a vertical bar graph to divide the data that made up the first graph by IP address.

For example if the first graph was reporting usage by active sessions it would include a bar for each of the top policies with a number at the end showing how many sessions were currently going through that policy. If one of the bars of the graph was then selected the new bar graph would show the traffic of that policy separated by either **Source Address**, **Destination Address** or **Destination Port**. As in the other window, the selection for the reported criteria is in the upper right corner of the pane. If the parameter was by source address there would be a bar for each of the IP addresses sending a session through the policy and the end of the bar would show how many sessions.

To go back to the previous window of information in the graphs select the Return link in the upper left of the pane.

Lower pane

The lower pane contains a spreadsheet of the information that the bar graph will derive their information from. The column headings will include:

- Policy ID
- Source Interface/Zone
- Destination Interface/Zone
- Action

- Active Sessions
- Bytes
- Packets

Network defense

This section describes in general terms the means by which attackers can attempt to compromise your network and steps you can take to protect it. The goal of an attack can be as complex as gaining access to your network and the privileged information it contains, or as simple as preventing customers from accessing your web server. Even allowing a virus onto your network can cause damage, so you need to protect against viruses and malware even if they are not specifically targeted at your network.

The following topics are included in this section:

- Monitoring
- Blocking external probes
- Defending against DoS attacks

Monitoring

Monitoring, in the form of logging, alert email, and SNMP, does not directly protect your network. But monitoring allows you to review the progress of an attack, whether afterwards or while in progress. How the attack unfolds may reveal weaknesses in your preparations. The packet archive and sniffer policy logs can reveal more details about the attack. Depending on the detail in your logs, you may be able to determine the attackers location and identity.

While log information is valuable, you must balance the log information with the resources required to collect and store it.

Blocking external probes

Protection against attacks is important, but attackers often use vulnerabilities and network tools to gather information about your network to plan an attack. It is often easier to prevent an attacker from learning important details about your network than to defend against an attack designed to exploit your particular network.

Attacks are often tailored to the hardware or operating system of the target, so reconnaissance is often the first step. The IP addresses of the hosts, the open ports, and the operating systems the hosts are running is invaluable information to an attacker. Probing your network can be as simple as an attacker performing an address sweep or port scan to a more involved operation like sending TCP packets with invalid combinations of flags to see how your firewall reacts.

Address sweeps

An address sweep is a basic network scanning technique to determine which addresses in an address range have active hosts. A typical address sweep involves sending an ICMP ECHO request (a ping) to each address in an address range to attempt to get a response. A response signifies that there is a host at this address that responded to the ping. It then becomes a target for more detailed and potentially invasive attacks.

Address sweeps do not always reveal all the hosts in an address range because some systems may be configured to ignore ECHO requests and not respond, and some firewalls and gateways may be configured to prevent ECHO requests from being transmitted to the destination network. Despite this shortcoming, Address sweeps are still used because they are simple to perform with software tools that automate the process.

Use the `icmp_sweep` anomaly in a DoS policy to protect against address sweeps.

There are a number of IPS signatures to detect the use of ICMP probes that can gather information about your network. These signatures include `AddressMask, Traceroute, ICMP.Invalid.Packet.Size`, and `ICMP.Oversized.Packet`. Include ICMP protocol signatures in your IPS sensors to protect against these probes/attacks.

Port scans

Potential attackers may run a port scan on one or more of your hosts. This involves trying to establish a communication session to each port on a host. If the connection is successful, a service may be available that the attacker can exploit.

Use the DoS anomaly check for `tcp_port_scan` to limit the number of sessions (complete and incomplete) from a single source IP address to the configured threshold. If the number of sessions exceed the threshold, the configured action is taken.

Use the DoS anomaly check for `udp_scan` to limit UDP sessions in the same way.

Probes using IP traffic options

Every TCP packet has space reserved for eight flags or control bits. They are used for communicating various control messages. Although space in the packet is reserved for all eight, there are various combinations of flags that should never happen in normal network operation. For example, the SYN flag, used to initiate a session, and the FIN flag, used to end a session, should never be set in the same packet.

Attackers may create packets with these invalid combinations to test how a host will react. Various operating systems and hardware react in different ways, giving a potential attackers clues about the components of your network.

The IPS signature `TCP.Bad.Flags` detects these invalid combinations. The default action is pass though you can override the default and set it to **Block** in your IPS sensor.

Configure packet replay and TCP sequence checking

The anti-replay CLI command allows you to set the level of checking for packet replay and TCP sequence checking (or TCP Sequence (SEQ) number checking). All TCP packets contain a Sequence Number (SEQ) and an Acknowledgement Number (ACK). The TCP protocol uses these numbers for error free end-to-end communications. TCP sequence checking can also be used to validate individual packets.

FortiGate units use TCP sequence checking to make sure that a packet is part of a TCP session. By default, if a packet is received with sequence numbers that fall out of the expected range, the FortiGate unit drops the packet. This is normally a desired behavior, since it means that the packet is invalid. But in some cases you may want to configure different levels of anti-replay checking if some of your network equipment uses non-RFC methods when sending packets.

Configure the anti-replay CLI command:

```
config system global
   set anti-replay {disable | loose | strict}
end
```

You can set anti-replay protection to the following settings:

- `disable` — No anti-replay protection.
- `loose` — Perform packet sequence checking and ICMP anti-replay checking with the following criteria:
- The SYN, FIN, and RST bit can not appear in the same packet.

- The FortiGate unit does not allow more than one ICMP error packet through before it receives a normal TCP or UDP packet.
- If the FortiGate unit receives an RST packet, and check-reset-range is set to strict, the FortiGate unit checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- `strict` — Performs all of the loose checking but for each new session also checks to determine of the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value for each new session. Strict anti-replay checking can also help prevent SYN flooding.

If any packet fails a check it is dropped.

Configure ICMP error message verification

Enable ICMP error message verification to ensure an attacker can not send an invalid ICMP error message.

```
config system global
   check-reset-range {disable | strict}
end
```

- `disable` — the FortiGate unit does not validate ICMP error messages.
- `strict` — enable ICMP error message checking.

If the FortiGate unit receives an ICMP error packet that contains an embedded IP(A,B) | TCP(C,D) header, then if FortiOS can locate the A:C->B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped. Strict checking also affects how the anti-replay option checks packets.

Protocol header checking

Select the level of checking performed on protocol headers.

```
config system global
   check-protocol-header {loose | strict}
end
```

- `loose` — the FortiGate unit performs basic header checking to verify that a packet is part of a session and should be processed. Basic header checking includes verifying that the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options are correct, etc.
- `strict` — the FortiGate unit does the same checking as above plus it verifies that ESP packets have the correct sequence number, SPI, and data length.

If the packet fails header checking it is dropped by the FortiGate unit.

Evasion techniques

Attackers employ a wide range of tactics to try to disguise their techniques. If an attacker disguises a known attack in such a way that it is not recognized, the attack will evade your security and possibly succeed. FortiGate security recognizes a wide variety of evasion techniques and normalizes data traffic before inspecting it.

Packet fragmentation

Information sent across local networks and the Internet is encapsulated in packets. There is a maximum allowable size for packets and this maximum size varies depending on network configuration and equipment limitations. If a packet arrives at a switch or gateway and it is too large, the data it carries is divided among two or more smaller packets before being forwarded. This is called fragmentation.

When fragmented packets arrive at their destination, they are reassembled and read. If the fragments do not arrive together, they must be held until all of the fragments arrive. Reassembly of a packet requires all of the fragments.

The FortiGate unit automatically reassembles fragmented packets before processing them because fragmented packets can evade security measures. This reassembly of packets affects TCP, UDP and IP packets. There can be some variation though in what process does the reassembling. The IPS engine, nTurbo and the kernel all can do defragmentation.

For example, you have configured the FortiGate unit to block access to the example.org web site. Any checks for example.com will fail if a fragmented packet arrives and one fragment contains `http://www.exa` while the other contains `mple.com/`. Viruses and malware can be fragmented and avoid detection in the same way. The FortiGate unit will reassemble fragmented packets before examining network data to ensure that inadvertent or deliberate packet fragmentation does not hide threats in network traffic.

Non-standard ports

Most traffic is sent on a standard port based on the traffic type. The FortiGate unit recognizes most traffic by packet content rather than the TCP/UDP port and uses the proper IPS signatures to examine it. Protocols recognized regardless of port include DHCP, DNP3, FTP, HTTP, IMAP, MS RPC, NNTP, POP3, RSTP, SIP, SMTP, and SSL, as well as the supported IM/P2P application protocols.

In this way, the FortiGate unit will recognize HTTP traffic being sent on port 25 as HTTP rather than SMTP, for example. Because the protocol is correctly identified, the FortiGate unit will examine the traffic for any enabled HTTP signatures.

Negotiation codes

Telnet and FTP servers and clients support the use of negotiation information to allow the server to report what features it supports. This information has been used to exploit vulnerable servers. To avoid this problem, the FortiGate unit removes negotiation codes before IPS inspection.

HTTP URL obfuscation

Attackers encode HTML links using various formats to evade detection and bypass security measures. For example, the URL www.example.com/cgi.bin could be encoded in a number of ways to avoid detection but still work properly, and be interpreted the same, in a web browser.

The FortiGate prevents the obfuscation by converting the URL to ASCII before inspection.

HTTP URL obfuscation types

Encoding type	Example
No encoding	http://www.example.com/cgi.bin/
Decimal encoding	http://www.example.com/cgi.bin/
URL encoding	http://www.example.com/%43%47%49%2E%42%49%4E%2F
ANSI encoding	http://www.example.com/%u0063%u0067%u0069%u002E%u0062%u0069%u006E/
Directory traversal	http://www.example.com/cgi.bin/test/../

HTTP header obfuscation

The headers of HTTP requests or responses can be modified to make the discovery of patterns and attacks more difficult. To prevent this, the FortiGate unit will:

- remove junk header lines
- reassemble an HTTP header that's been folded onto multiple lines
- move request parameters to HTTP POST body from the URL

The message is scanned for any enabled HTTP IPS signatures once these problems are corrected.

HTTP body obfuscation

The body content of HTTP traffic can be hidden in an attempt to circumvent security scanning. HTTP content can be GZipped or deflated to prevent security inspection. The FortiGate unit will uncompress the traffic before inspecting it.

Another way to hide the contents of HTTP traffic is to send the HTTP body in small pieces, splitting signature matches across two separate pieces of the HTTP body. The FortiGate unit reassembles these 'chunked bodies' before inspection.

Microsoft RPC evasion

Because of its complexity, the Microsoft Remote Procedure Call protocol suite is subject to a number of known evasion techniques, including:

- SMB-level fragmentation
- DCERPC-level fragmentation
- DCERPC multi-part fragmentation
- DCERPC UDP fragmentation
- Multiple DCERPC fragments in one packet

The FortiGate unit reassembles the fragments into their original form before inspection.

Defending against DoS attacks

A denial of service is the result of an attacker sending an abnormally large amount of network traffic to a target system. Having to deal with the traffic flood slows down or disables the target system so that legitimate users can not use it for the duration of the attack.

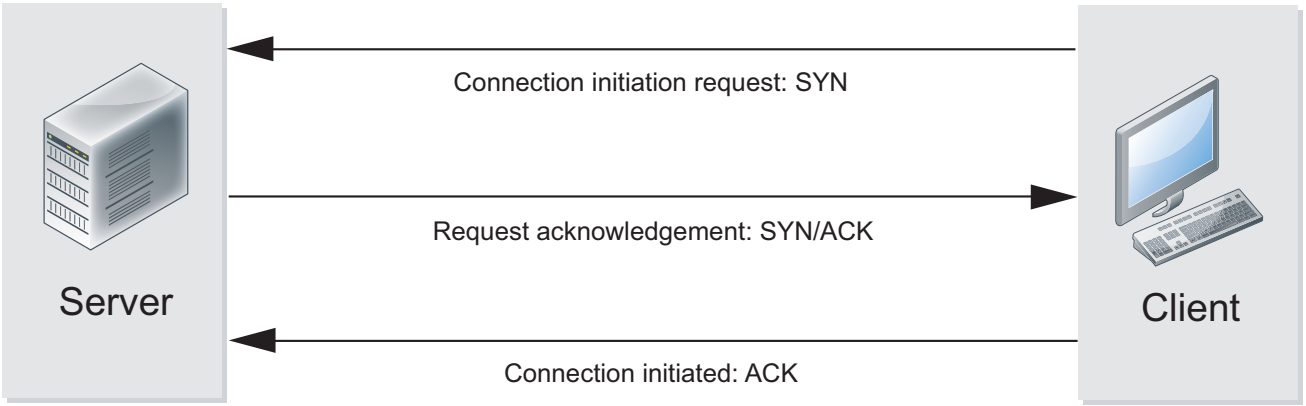
Any network traffic the target system receives has to be examined, and then accepted or rejected. TCP, UDP, and ICMP traffic is most commonly used, but a particular type of TCP traffic is the most effective. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are started between systems.

The “three-way handshake”

Communication sessions between systems start with establishing a TCP/IP connection. This is a simple three step process, sometimes called a “three-way handshake,” initiated by the client attempting to open the connection.

1. The client sends a TCP packet with the SYN flag set. With the SYN packet, the client informs the server of its intention to establish a connection.
2. If the server is able to accept the connection to the client, it sends a packet with the SYN and the ACK flags set. This simultaneously acknowledges the SYN packet the server has received, and informs the client that the server intends to establish a connection.
3. To acknowledge receipt of the packet and establish the connection, the client sends an ACK packet.

Establishing a TCP/IP connection



The three-way handshake is a simple way for the server and client to each agree to establish a connection and acknowledge the other party expressing its intent. Unfortunately, the three-way handshake can be used to interfere with communication rather than facilitate it.

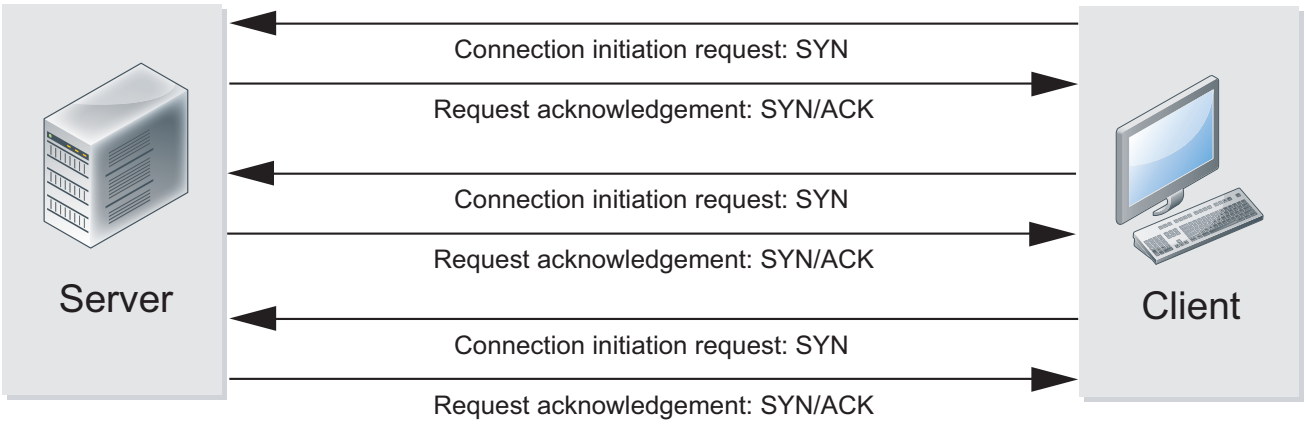
SYN flood

When a client sends a SYN packet to a server, the server creates an entry in its session table to keep track of the connection. The server then sends a SYN+ACK packet expecting an ACK reply and the establishment of a connection.

An attacker intending to disrupt a server with a denial of service (DoS) attack can send a flood of SYN packets and not respond to the SYN+ACK packets the server sends in response. Networks can be slow and packets can get lost so the server will continue to send SYN+ACK packets until it gives up, and removes the failed session from

the session table. If an attacker sends enough SYN packets to the server, the session table will fill completely, and further connection attempts will be denied until the incomplete sessions time out. Until this happens, the server is unavailable to service legitimate connection requests.

A single client launches a SYN flood attack

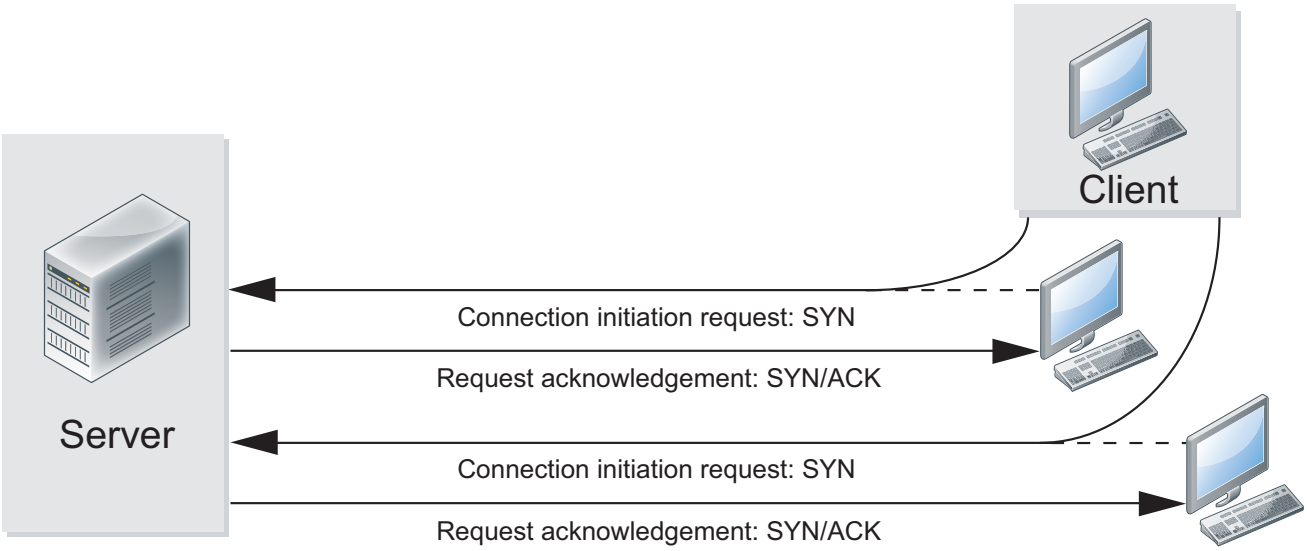


SYN floods are seldom launched from a single address so limiting the number of connection attempts from a single IP address is not usually effective.

SYN spoofing

With a flood of SYN packets coming from a single attacker, you can limit the number of connection attempts from the source IP address or block the attacker entirely. To prevent this simple defense from working, or to disguise the source of the attack, the attacker may spoof the source address and use a number of IP addresses to give the appearance of a distributed denial of service (DDoS) attack. When the server receives the spoofed SYN packets, the SYN+ACK replies will go to the spoofed source IP addresses which will either be invalid, or the system receiving the reply will not know what to do with it.

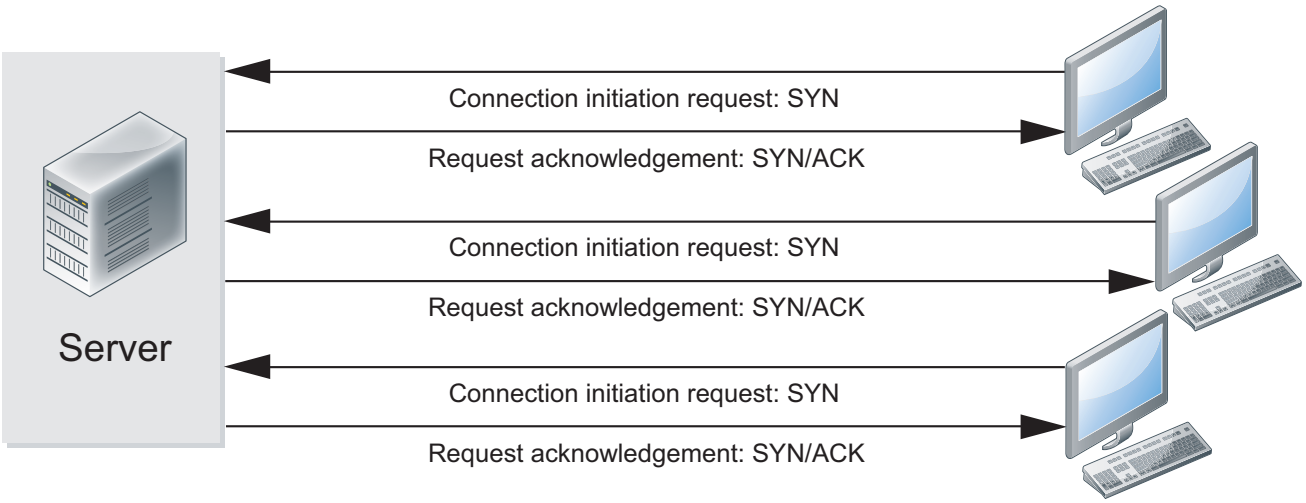
A client launches a SYN spoof attack



DDoS SYN flood

The most severe form of SYN attack is the distributed SYN flood, one variety of distributed denial of service attack (DDoS). Like the SYN flood, the target receives a flood of SYN packets and the ACK+SYN replies are never answered. The attack is distributed across multiple sources sending SYN packets in a coordinated attack.

Multiple attackers launch a distributed SYN flood



The distributed SYN flood is more difficult to defend against because multiple clients are capable of creating a larger volume of SYN packets than a single client. Even if the server can cope, the volume of traffic may overwhelm a point in the network upstream of the targeted server. The only defence against this is more bandwidth to prevent any choke-points.

Configuring the SYN threshold to prevent SYN floods

The preferred primary defence against any type of SYN flood is the DoS anomaly check for `tcp_syn_flood` threshold. The threshold value sets an upper limit on the number of new incomplete TCP connections allowed per second. If the number of incomplete connections exceeds the threshold value, and the action is set to **Pass**, the FortiGate unit will allow the SYN packets that exceed the threshold. If the action is set to **Block**, the FortiGate unit will block the SYN packets that exceed the threshold, but it will allow SYN packets from clients that send another SYN packet.

The tools attackers use to generate network traffic will not send a second SYN packet when a SYN+ACK response is not received from the server. These tools will not “retry.” Legitimate clients will retry when no response is received, and these retries are allowed even if they exceed the threshold with the action set to **Block**.

SYN proxy

FortiGate units with network acceleration hardware, whether built-in or installed in the form of an add-on module, offer a third action for the `tcp_syn_flood` threshold. Instead of **Block** and **Pass**, you can choose to **Proxy** the incomplete connections that exceed the threshold value.

When the `tcp_syn_flood` threshold action is set to **f**, incomplete TCP connections are allowed as normal as long as the configured threshold is not exceeded. If the threshold is exceeded, the FortiGate unit will intercept incoming SYN packets from clients and respond with a SYN+ACK packet. If the FortiGate unit receives an ACK response as expected, it will “replay” this exchange to the server to establish a communication session between the client and the server, and allow the communication to proceed.

Other flood types

UDP and ICMP packets can also be used for DoS attacks, though they are less common. TCP SYN packets are so effective because the target receives them and maintains a session table entry for each until they time out. Attacks using UDP or ICMP packets do not require the same level of attention from a target, rendering them less effective. The target will usually drop the offending packets immediately, closing the session.

Use the `udp_flood` and `icmp_flood` thresholds to defend against these DoS attacks.

DoS policies

DDoS attacks vary in nature and intensity. Attacks aimed at saturating the available bandwidth upstream of your service can only be countered by adding more bandwidth. DoS policies can help protect against DDoS attacks that aim to overwhelm your server resources.

DoS policy recommendations

- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received.
- It is important to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, although your network may require very different values.
- One way to find the correct values for your environment is to set the action to **Pass** and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

GUI and CLI - what you may not know

The Graphic User Interface (GUI) is designed to be as intuitive as possible but there are always a few things that are left out because to put all of that information on the interface would clutter it up to the point where it wouldn't be graphical and intuitive anymore.

This section is made up of knowledge that will make working with the both of the management interfaces easier because you wont have to find out about things like field limitations through trial and error. Some of it has to do with changing in how navigation in the GUI has changed.

The section includes the topics:

- Mouse Tricks
- Changing the default column setting on the policy page
- Naming Rules and Restrictions
- Character Restrictions
- Length of Fields Restrictions
- Object Tagging and Coloring
- Numeric Values
- Selecting options from a list
- Enabling or disabling options
- To Enable or Disable Optionally Displayed Features

Mouse tricks

In previous version of the firmware much of the navigation, editing or choosing of options in the Web-based Manager was carried out by using the mouse in combination with a number of icons visible on the interface. This version of the firmware makes more extensive use of the right or secondary mouse button as well as the “drag and drop” feature. If you are used to the old Web-based Manager interface you will notice that a number of the options at the top of the display window are not there anymore or there are fewer of them.
